INFECTIOUS HEPATITIS: A REVIEW OF 200 CASES

CHARLES L. HOAGLAND, M.D.
and
LIEUTENANT COMMANDER ROBERT E. SHANK (MC), U.S.N.R.
New York

There have been few wars during the past century in which infectious hepatitis, or "epidemic jaundice," as it is frequently called, has not been responsible for a significant portion of the total noncombatant illness. With the possible exception of the War for Independence, jaundice has appeared in every campaign in which the armed forces of the United States have participated.[1] During the present war epidemic hepatitis has been a grave military problem, and although the total number of cases among all the military forces of the world will be revealed only at some later date, there is sufficient evidence from published reports to indicate that it is one of the most important noncombatant illnesses among troops of all branches of military service.[2] Outbreaks of jaundice are, moreover, not limited to members of the fighting forces. It has been commonly encountered in sporadic and endemic form in civilian communities for many decades. Camps, boarding schools, orphanages and other eleemosynary institutions have been particularly favorable sites for outbreaks of infectious hepatitis. In several instances the disease has reached epidemic proportions in the community surrounding the institution where the initial cases occurred. During the winter of 1921-1922 the State of New York was visited over a very wide area by so-called infectious jaundice, with one report alone recording over 700 cases.[3]

MATERIAL

The present report is concerned with a partial analysis of the results of clinical and metabolic studies and of the effects of various forms of treatment on 200 patients with infectious hepatitis admitted to the Rockefeller Institute Hospital between July 3, 1944 and April 1, 1945. Except for 2 civilians, the patients were commissioned officers and enlisted personnel from the Second, Third, Fourth and Fifth Naval Districts. Data on age and sex distribution in these cases are shown in table 1. The purpose of the study was threefold: (1) to define, as far as biochemical and metabolic technics for the evaluation of hepatic function permit, the extent to which the liver is damaged in the average nonfatal case of infectious hepatitis; (2) to ascertain to what extent the damage is repaired, and the length of time required for complete or maximal recovery of hepatic function, and (3) to assess the effect of various therapeutic measures, currently held to be of value in hastening regeneration following damage to the liver, on the length of time required for recovery of normal hepatic function.

CLINICAL MANIFESTATIONS OF INFECTIOUS HEPATITIS

Qualitatively, the clinical features of the patients with infectious hepatitis described in this study have been remarkably constant, with, however, differences in the severity of symptoms, ranging all the way from slight malaise in some to a state of toxemia in exceptional cases not unlike that seen in acute yellow atrophy. In approximately 85 per cent of patients a prodromal period lasting from one to nine days has preceded the appearance of jaundice; in a few it has been ten to fifteen days and in rare cases twenty to twenty-five days (table 2). Approximately 10 per cent of the patients complained of jaundice as the initial symptom. A number of patients, approximately 5 per cent, claimed that they did not have subjective symptoms either in the preicteric phase of the disease or thereafter. In these cases medical help had been sought because of the development of icterus. In most patients, however, a well defined preicteric stage was characterized by lassitude and fatigue, nausea and almost complete anorexia. An initial elevation of temperature, between 100 and 103 F., has occurred in approximately one half of the cases. In most instances the appearance of jaundice coincided with the end of the initial symptoms and the beginning of convalescence.

The degree of icterus varied greatly, from a local condition limited principally to the periphery of the scleras to one of intense, generalized yellow-bronze pigmentation involving the scleras, the whole skin and the mucous membranes. Undoubtedly a few of the cases with only slight icterus would have escaped clinical detection had it not been for associated signs of liver disease, including anorexia, nausea and hepatomegaly with tenderness. Although nausea was common, vomiting was infrequent. Headache was a presenting sign in approximately one third of the cases (table 3).

Abdominal discomfort, amounting to frank pain in the exceptional case, was common. Frequently there were complaints of epigastric pain and only rarely of pain in the upper right quadrant. Liver enlargement was present on admission in 51 per cent of the patients, with hepatic tenderness in 38 per cent (table 4). Most patients presented some degree of hepatic tenderness and hepatomegaly at some time during the course of the disease. Enlargement of the spleen occurred in 10 per cent of the cases. Bradycardia of variable degree was present at some stage of the disease in many of the patients showing moderate to severe icterus. Pruritus of all degrees of severity occurred in 46 per cent of cases. The appearance of bile in the urine was observed by the patient in nearly every instance within a period of one to three days before the appearance of jaundice in the scleras. Less frequently the patient had also noted light or clay colored stools during this period.

Table 1.—*Age and Sex Distribution in 200 Cases of Infectious Hepatitis*

Age in Years	Sex		Number of Cases	Per Cent of Cases
	Male	Female		
16 - 20	59	0	59	29.5
21 - 25	70	4	74	37.0
26 - 30	27	2	29	14.5
31 - 35	23	1	24	12.0
36 - 40	12	0	12	6.0
41 - 45	1	0	1	0.5
46 - 50	1	0	1	0.5
Total	193	7	200	100.0

Frank recrudescence of the disease, a state recognized by deterioration of the patient's condition during recovery and leading to a return of clinical symptoms, was recognized in 6 cases. In a larger number of cases, however, amounting to approximately 15 per cent of the group, there were periods when liver function tests revealed values which were more abnormal than those previously observed. These periods may have represented adverse phases of the disease which were not sufficiently well defined to be reflected in a return of clinical symptoms. A history of previous episodes of acute infectious hepatitis was given by 5 patients, among whom 1 recalled three separate attacks during the preceding ten years. A history of recent contact with other cases of infectious hepatitis was given frequently.

DIFFERENTIAL DIAGNOSIS

In most cases the differential diagnosis of infectious hepatitis presented little or no difficulty. The sudden onset of a train of symptoms, largely referable to the liver and digestive tract, in a group of young men previously in excellent health, resulted in a clinical picture hard to confuse with other diseases. This was especially true in patients from regions in which the incidence of hepatitis had been relatively high, with the result that the physicians in these areas were sensitized to its occurrence. Nevertheless erroneous tentative diagnoses were common, and in some cases the referring diagnosis had to be changed entirely, owing to the appearance of new clinical phenomena during the course of the patient's illness. The most common mistakes in diagnosis were made in the preicteric phase of the disease and consisted in confusion of hepatitis with upper respiratory infections, atypical pneumonia and infectious mononucleosis. Weil's disease, amebic hepatitis, malarial hepatitis, hemolytic jaundice and obstructive lesions of the biliary tract were occasionally ventured as alternative diagnoses in a few cases after the appearance of jaundice. The relatively high incidence of hepatitis in endemic areas from which the patients were chiefly supplied, the relative infrequency of obstructive lesions of the biliary tract in men of military age and the fact that the patients came from a group of individuals previously selected for military service on the basis of freedom from chronic ill health and physical disability combined to offer favorable circumstances for correct clinical diagnosis.

TESTS OF HEPATIC FUNCTION

It is generally accepted that no single test of hepatic function has been devised which gives an adequate index of the physiologic condition of the liver. Little consideration, however, has been given to a study of the kind and minimal number of hepatic function tests which should be performed in order to give maximal information necessary for the intelligent clinical care of patients with various types of hepatic insufficiency.

Data on weekly determinations of several tests of metabolism and liver function, covering the clinical stages of hepatitis from acute onset to the end of convalescence, were obtained in each of the cases reported in this series. Determinations on the plasma included albumin, globulin, fibrinogen, prothrombin time, alkaline phosphatase, free and esterified cholesterol, phospholipid, total lipid, vitamin A, sulfobromophthalein retention and bilirubin. Weekly cephalin flocculation tests were made on the serums. A complete analysis of data secured from multiple serial tests of liver function in infectious hepatitis will appear in a subsequent report.

Except in the infrequent case presenting signs of chronic liver disease, all abnormal values for the various constituents of the blood in patients with infectious hepatitis returned to normal within the period of time covered by hospitalization. The average rate at which values for an individual test of liver function returned to normal appeared to bear a very definite relation to the rate at which values for other tests fell within the normal range. Notwithstanding the fact that the tests were chosen in a manner calculated to cover the greatest possible diversity of function, there was a surprising correlation in the degrees of alteration shown by the results of the various tests at any time during the course of the disease in any given case. There was likewise a remarkably close agreement in general between the results of any given series of tests and the clinical impression gained by a study of the patient at the time the tests were performed. Data on the correlation of the results of the various tests of liver function with respect to one another and with the clinical course of the disease have been compiled in table 5. Multiple tests of liver function appeared to have their greatest usefulness in

Table 2.—*Interval Between Onset of Symptoms and Appearance of Jaundice in 200 Cases of Infectious Hepatitis*

Interval in Days	Number of Cases	Per Cent of Cases
0 - 4	80	40.0
5 - 9	92	46.0
10 - 14	18	9.0
15 - 19	5	2.5
20 - 24	4	2.0
25 - 29	0	0.0

	200	100

the late stages of convalescence when it was no longer certain from the clinical condition of the patient whether the activity of the disease process had subsided. At this stage in the disease the greatest degree of dissociation among the results of the various tests of liver function was encountered. In approximately 10 per cent of the cases clinical convalescence appeared to be complete two to three weeks, and sometimes longer, before the results of certain liver function tests (notably the retention of sulfobromophthalein and the ratio of free to total cholesterol) had fallen within the accepted range of normal.

Table 3.—*Symptoms Occurring in the Preicteric Phase in 200 Patients with Infectious Hepatitis*

Symptoms	Number of Cases	Per Cent of Cases
General symptoms		
Lassitude and fatigue	137	68.5
Pruritus	93	46.5
Fever	83	41.5
Headache	53	26.5
Chills	34	17.0
Upper respiratory infection	31	15.5

Syncope	16	8.0
Epistaxis	9	4.5
Cough	8	4.0
Urticaria	6	3.0
Symptoms referable to disease of the liver or gastrointestinal tract		
Anorexia	184	92.0
Urine dark	181	90.5
Nausea	158	79.0
Vomiting	117	58.5
Abdominal pain	114	57.0
Acholic stools	109	54.5
Constipation	45	22.5
Diarrhea	19	9.5
No preicteric symptoms	15	7.5

Deviation from the normal values for percentage retention of sulfobromophthalein paralleled in general the deviation from the normal of simultaneous values obtained for plasma bilirubin. When clinical jaundice was evident, the use of both tests gave little information which would not have been revealed by either alone. However, in the incipient stages of the disease, and in the late stage of convalescence, when the bilirubin concentration in the plasma was normal or nearly so, the sulfobromophthalein retention proved to be much more sensitive than the test for bilirubin. It was particularly helpful in indicating the presence of latent hepatic insufficiency. Since clinical signs of the disease were often minimal or absent in this phase of the disease, it is evident that a considerable number of patients would have been discharged before they had regained complete recovery of liver function had the sulfobromophthalein tests not been performed and a normal value required before the patient was permitted to return to active duty.

The level of vitamin A in the plasma was in the low range of normal or diminished in every case, and in general this diminution was proportional to the clinical severity of the disease. The vitamin A content of the plasma began to rise early in convalescence and was always well within the normal range by the time convalescence was established. Several factors are probably at work in the production of lowered values for vitamin A in the plasma during the acute stages of infectious hepatitis: (1) lowered intake and faulty absorption of the vitamin, due respectively to anorexia and to deviation of the bile salts from the intestinal tract; (2) decreased storage capacity of the diseased liver for vitamin A, with consequent dependence of the height of the plasma level on the amount and rate of ingestion of the vitamin. Moreover, it is likely that in febrile diseases in which the plasma vitamin A is low, as in rheumatic fever and pneumonia, there occurs a more rapid rate of utilization or destruction of the vitamin than in the normal subject.[4]

The plasma prothrombin time was increased only in those cases of infectious hepatitis presenting severe symptoms and evidence of extensive destruction of the hepatic parenchyma as revealed by other tests of liver function. In most patients having an increased prothrombin time, the parenteral administration of menadione resulted in prompt return of the values to the normal range.

The total protein, albumin and globulin of plasma were determined at weekly intervals on 150 patients with acute infectious hepatitis. The acute phase of the disease was found in some patients to be accompanied by a decrease in the total protein, an increase in globulin and a decrease in the albumin fraction. During convalescence these changes were reversed, and on clinical recovery the ratio of albumin/globulin was well within the normal range. Twenty-one per cent of the 150 patients had levels of plasma protein less than 6 Gm. per hundred cubic centimeters at some time during the acute phase of the disease. At this time the concentration of plasma albumin was less than 4 Gm. per hundred cubic centimeters in 44 per cent of the patients, while plasma globulin greater than 3 Gm. per hundred cubic centimeters was observed in 16 per cent. In 40 per cent of patients acutely ill of hepatitis, the albumin/globulin ratio was less than 1.5.

Total lipid and phospholipid concentrations of the plasma were determined at weekly intervals during the entire course of the disease in more than 100 patients in order to learn to what extent aberrant fat metabolism, believed to occur in this disease, was reflected in altered plasma lipid concentration. During the acute stages no important changes were manifest. Within a few days after the onset of jaundice, however, elevation in the lipid and phospholipid concentrations of the plasma was found, occasionally reaching 200 per cent of the normal concentration of lipid and 300 per cent concentration of phospholipid; and usually this elevation persisted until the onset of convalescence, when there was a rapid restoration of the concentration of the lipids to normal levels.

Table 4.—*Common Physical Findings in 200 Patients with Infectious Hepatitis*

CHANGES IN THE CELLULAR ELEMENTS OF THE BLOOD

The erythrocyte count in the majority of patients was maintained at a normal level throughout the course of the disease. A hyperchromic anemia of moderate degree, however, was encountered in those patients presenting unusually severe symptoms of hepatitis and in cases showing chronic damage to the liver persisting over periods of several months or more. The leukocyte count varied from 4,000 to 10,000 initially in the disease process. In some cases there was a moderate leukopenia early in the course of the disease. However, normal values for the leukocytes were recorded in all cases in the period of beginning convalescence. Lymphocytosis to an extent of 45 to 70 per cent of the total leukocyte count was noted frequently early in the disease. In most cases the erythrocyte sedimentation rate was normal or only slightly elevated during the first several days of the disease. It frequently increased to values of 25 to 50 mm. per hour during the period of convalescence, however, and gradually fell to normal limits late in the period of recovery.

THE CARDIOVASCULAR AND AUTONOMIC NERVOUS SYSTEMS IN INFECTIOUS HEPATITIS

Bradycardia of some degree occurred in 25 per cent of the patients with infectious hepatitis and in general was confined to those cases manifesting moderate to severe clinical symptoms of the disease. In some cases it persisted throughout the period of convalescence. Search was made in each case of infectious hepatitis for other symptoms referable to the autonomic nervous system. Hypotension, with systolic pressures below 110 mm. of mercury, was of frequent occurrence. Sinus irregularity of the heart occurred frequently, both with and without bradycardia. In these cases electrocardiographic tracings frequently revealed changes in the site of origin of the atrioventricular impulse. Partial heart block, as revealed by lengthening of the PR interval, occurred occasionally in a few patients. In these cases abolition of the partial block could be achieved by the parenteral administration of atropine. The effect of atropine was temporary, however, and in some patients little or no effect was observed. Symptoms which could be definitely attributed to pylorospasm were elicited in only 2 cases. Intestinal hyperperistalsis as such was not recognized, but in most of the severe cases repeated reference was made to vague abdominal pain during acute and convalescent stages alike.

The fact that bradycardia and in some instances prolongation of the PR interval could be abolished by atropine favors the hypothesis that vagal stimulation due to some unexplained process was at work in the production of the cardiovascular phenomenon.[5] Against this hypothesis, however, is the fact that in several cases no detectable changes in the delayed PR interval occurred following atropine in spite of the fact that sufficient drug was given to produce a moderate tachycardia. Moreover, by reference to table 6 it will be observed that no relationship could be demonstrated between the heart rate and the length of the PR interval. If the prolongation of the PR interval was due solely to vagotonia, an accompanying bradycardia would have been expected.

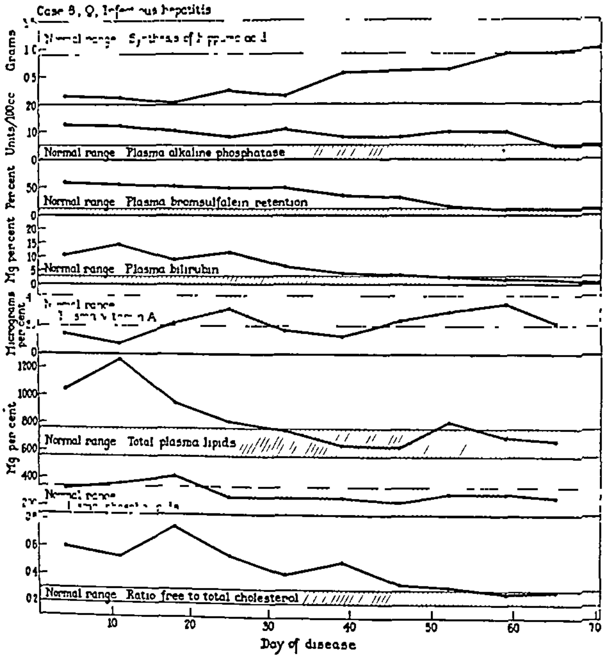
SPECIFIC THERAPY IN INFECTIOUS HEPATITIS

Except in the occasional case in which the syndrome becomes chronic, infectious hepatitis is apparently a self-limited disease.[6] Until more specific information is at hand concerning the metabolic aberrations in this disease, it seemed wise to limit attempts at therapy to those measures which are believed on the basis of animal experimentation to hasten repair of the damaged liver. In the present series the following types of therapy have been tried; namely, the administration of methionine, choline and crude liver extract to three groups of selected patients respectively. A fourth group, to which isotonic solution of sodium chloride was given, constituted a control series. All four groups were maintained on diets containing on the average 150 Gm. of protein, 60 Gm. of fat and 400 Gm. of carbohydrate throughout the period of observation.

The rationale for the administration of methionine in the treatment of patients with liver disease is derived from results obtained in the prevention of chloroform injury to the liver in protein depleted dogs.[7] Claims have been made both for [8] and against [9] its efficacy in the treatment of infectious hepatitis. Only patients admitted early in the course of the disease were selected for trial with methionine. Other groups, strictly comparable with respect to time of onset of the disease before institution of therapy, were selected for treatment with saline solution, liver extract and choline. Strict rotation of patients among the four groups was observed throughout.



Comparative values for the common tests of liver function employed in this study in a typical case of infectious hepatitis of average duration and severity.

Table 6.—*Table Showing Lack of Correlation Between Heart Rate and Increase in PR Interval in Infectious Hepatitis*

Heart Rate	Total Number of Determinations	Number of Determinations with PR Interval 0 20 or Over	Per Cent
40 - 50	3	1	..
50 - 60	16	3	19
60 - 70	68	15	22
70 - 80	82	19	23
80 - 90	83	13	16
90 -100	47	11	23
100 -110	13	0	..

Sixteen patients comprise the group treated with methionine. Each patient received 5 Gm. of a racemic mixture of the amino acid in 200 cc. of isotonic solution of sodium chloride intravenously on admission and daily thereafter for ten days. The material was well tolerated and induced no adverse signs or symptoms. Although the group was fairly small, it appeared from objective clinical considerations, including a study of the average net change in weight, and from results of frequent tests of liver function, that the course of the disease was not perceptibly influenced by this form of treatment. Since the patients who received methionine were at the same time receiving diets moderately high in protein, the results do not permit a statement regarding the possible effectiveness of supplementary methionine in the presence of an inadequate protein intake (table 7).

Table 7.—*Comparison Respectively Between Effects of Methionine, Choline, Liver Extract and Saline Solution on the Average Period Required for Recovery in Patients with Infectious Hepatitis*

Medication	Number of Patients	Net Change in Weight in Hospital, Kg.	Average Duration of Illness, Days
Intravenous methionine	16	+2 9	53 5
Oral choline	29	+3 1	50.7
Intravenous crude liver extract	34	+3 5	48 9
Intravenous saline solution (control group)	31	+3 1	51 5

The use of choline in the treatment of acute hepatic insufficiency is based on a rationale somewhat similar to that proposed for methionine. Both compounds are lipotropic,[10] and in the normal animal methionine may be considered nutritionally equivalent to choline.[11] In view of the widely essential role of the liver in intermediary metabolism, it is not justified to assume in our present incomplete state of knowledge of liver processes that methionine is nutritionally equivalent to choline in hepatic insufficiency. It was deemed important, therefore, to give choline a separate trial in the treatment of infectious hepatitis in order to learn whether the syndrome would be favorably modified thereby.

Twenty-five patients comprise the group which received choline. Each patient received 5 Gm. of choline hydrochloride in divided doses on admission and daily thereafter for ten days. The material was well tolerated in each case. However, no effect was noted on the clinical course of the disease which could be attributed to choline therapy. An average duration of illness of 50.7 days for the group of patients treated with choline was not significantly different from that of 53.5 for methionine or 51.5 days for the control group receiving only saline solution. The average gain in weight during convalescence for the patients in this group was approximately the same as in the control group.

The rationale for the administration of crude liver extract to patients with infectious hepatitis is harder to assess. Its use in the treatment of this disease was prompted by promising results which we have obtained during the past three years following its administration intravenously in large amounts to patients with cirrhosis of the liver.[12] Thirty-four patients with infectious hepatitis were treated daily with a specially prepared aqueous extract of Cohn's fraction G of liver[13] in amounts of 10 cc., diluted to 50 cc. with saline solution and given intravenously over a period of ten days following admission of the patient to the hospital. Careful preliminary tests for sensitivity and toxicity were carried out in every case before the full dose of 10 cc. was given. The material was well tolerated, and no adverse effects were observed in any patient. The difference between an average period of 48.9 days for the patients receiving liver extract and 51.5 days for the alternate control group receiving only saline solution was not considered significant. No significant difference in average gain in weight was recorded for this group over the control group or over the groups treated with choline and methionine.

TABLE 8.—*Effect of a Regimen of Rest on the Duration of Convalescence in Infectious Hepatitis*

Interval Between Appearance of First Symptoms and Hospitalization, Days	Number of Patients in Group	Average Period in Hospital, Days	Average Duration of Illness, Days	Standard Error
1 - 14..........	108	37.1	46.3	1.9
15 - 29..........	62	30.8	51.1	1.9
30 and more....	19	31.8	80.8	9.0

In none of the foregoing groups is the number of patients particularly large. It should be kept in mind, however, that the groups were made up of men of nearly the same age, presenting approximately the same degree of severity of the disease, and all in nearly the same stage of hepatitis when therapy was begun. The patients, moreover, had been in excellent health prior to the onset of the disease and were entirely free from complications of any sort other than hepatitis. Smaller numbers in each group were required, therefore, to yield significant data than would have been the case had there been differentials in age and sex and variability in the previous states of health of the patients.

EFFECT OF HOSPITALIZATION AND REST ON LENGTH OF TIME REQUIRED FOR CONVALESCENCE IN INFECTIOUS HEPATITIS

In an effort to ascertain those factors in the clinical care of patients with infectious hepatitis which affect the duration of convalescence, study was made of the effect of hospitalization and rest and of activity on the clinical course of the disease. Whenever possible, patients were transferred promptly from outlying naval districts to the Rockefeller Hospital on the appearance of the first unequivocal signs of hepatitis. Here a rigid routine of bed rest and restricted activity was imposed until convalescence was well under way. Some activity was permitted when the clinical condition of the patients appeared to warrant it and was increased gradually until it was deemed safe to permit the patient to be up and about the ward ad libitum. When all objective signs of the disease had disappeared and there was no longer any laboratory evidence of hepatic dysfunction, the patient was permitted one to three hours of liberty from the hospital each afternoon, having first been warned against undue physical exertion and the consumption of food and alcohol. Each patient was further told that any infraction of these rules would result in prompt cancellation of the privilege of liberty and jeopardize the granting of a routine of ten days' experimental period of sick leave on convalescence. In most instances these rules of conduct were respected.

Although it is now generally conceded that the clinical course of infectious hepatitis is favorably modified by strict adherence on the part of the patient to a regimen of rest and relative inactivity,[14] it had not always been possible to enforce such restrictions before admission of the patient to our service. Many patients had become ill at sea under circumstances in which adequate hospitalization and clinical care were difficult or impossible to carry out; some patients had been sent to port hospitals for study and diagnosis, with consequent delay of several weeks before transfer to the Rockefeller Hospital could be carried out. In yet another group the diagnosis was sufficiently equivocal in the early stages of illness to result in a prolonged period of observation, with delay in transfer. It became of interest, therefore, to ascertain what the overall effect of these circumstances might have been on the duration of convalescence and the severity of the attack in the average case of infectious hepatitis. The following groups were recognized: 1. Patients admitted to the Rockefeller Hospital within a period of fourteen days following the onset of the first unequivocal symptoms of infectious hepatitis. 2. Patients admitted within a period of fourteen to twenty-eight days following the onset of symptoms. 3. Patients who for the reasons stated were not admitted to our service until thirty or more days after the onset of the first symptoms of hepatitis. No cases of chronic liver disease or of hepatitis with complications were included in any of the three groups. Since all cases of infectious hepatitis recognized as such were sent through a blanket order from outlying naval districts to the Rockefeller Hospital, it has been assumed that the factors contributing to delay in transfer of the patients to the hospital were chiefly those which have been outlined, namely delay in reaching port, difficulties in diagnosis, and so on. A few patients had been promptly and effectively hospitalized in the interval between the appearance of the first symptoms of the disease and transfer of the patient to this hospital. Most patients, however, had been permitted activity as desired as soon as the acute stages of the disease had passed.

Graphic presentation of the effect of prompt and delayed institution of a regimen of rest and relative inactivity on the duration of convalescence in infectious hepatitis is shown in table 8. A consideration of the standard error indicates a questionable difference between 46.3 days for the average duration of illness in group 1 and an average duration of 51.1 days in group 2. The difference, therefore, may or may not be significant. There is no doubt, however, of the significance of the difference in the periods of convalescence between groups 1 and 2 and of group 3, with an average duration of 80.8 days. Since the essential difference among the various groups with respect to this analysis resided solely in the number of days antedating the period of restriction of physical activity imposed at the Rockefeller Hospital, it would appear that a regimen of hospitalization and restriction of activity imposed as late as thirty days following the onset of hepatitis had appreciably shortened the period of convalescence.

RECRUDESCENCE OF INFECTIOUS HEPATITIS FOLLOWING A PERIOD OF SICK LEAVE

While recrudescence amounting to definite deterioration of the patient's clinical condition during the course of convalescence was fortunately rare, evidence obtained from a careful analysis of 200 cases during recovery from hepatitis indicates that a large number of the patients showed some evidence of a temporary recrudescence following a period of apparent clinical recovery. Of various tests of liver function which were repeated serially on these patients, the sulfobromophthalein retention test proved most helpful in enabling us to detect evidence of recurrent hepatitis in patients in whom there was apparent complete convalescence and who as a consequence were granted a test period of ten days' leave from the hospital. Evaluation of the hepatic status of each patient was carried out immediately on the patient's return, including tests of sulfobromophthalein retention, plasma bilirubin and cephalin flocculation. Of the total group 18.5 per cent showed an abnormal elevation in the sulfobromophthalein retention during the convalescent period after sulfobromophthalein retention and the bilirubin concentration had reached normal or approximately normal levels. Of these, 82 per cent showed this reversal directly following the onset of a ten day period of sick leave. All cases showed an eventual return of the sulfobromophthalein retention to the normal range. In nearly all cases additional evidence was found of hepatic dysfunction, consisting of enlargement of the liver, with tenderness in some, complaints of fatigue in others and in certain cases of anorexia and abdominal pain. In several patients the cephlin flocculation test was positive. In a few there was a measurable elevation of the bilirubin. The total period of convalescence for this group was considerably lengthened over the group in which there were no evidences of hepatic dysfunction following return from sick leave. The average additional period of time required for convalescence in the group showing recrudescence varied from three days to ten weeks, with an average period of twenty days.

The percentage of patients who may be expected to develop signs of chronic liver disease following convalescence from an acute attack of hepatitis is not known with certainty at the present time. The incidence has been said to be low.[6] However, objective criteria for residual damage were not met in many instances or patients followed for long enough periods of time to have warranted the judgment that they had fully recovered. Establishment of adequate criteria which will permit early recognition of residual damage to the liver following an attack of infectious hepatitis is one of the major problems waiting to tax the ingenuity of the postwar worker in the field of liver disease.

SUMMARY

Qualitatively the clinical features observed in 200 cases of infectious hepatitis were remarkably constant, consisting of an acute febrile prodromal period with an average of 6.2 days' duration before the onset of clinical icterus. Quantitatively, however, there were differences in the severity of symptoms ranging all the way from slight malaise in some patients to a state of toxemia in exceptional cases not unlike that seen in acute yellow atrophy.

In most cases the differential diagnosis presented little difficulty, particularly after the onset of icterus. In the preicteric stage of the disease, however, it was frequently confused with upper respiratory infections, atypical pneumonia and infectious mononucleosis.

Multiple tests of liver function were performed at weekly intervals on each patient. Of these the plasma bilirubin, the ratio of free to total cholesterol in the plasma and the plasma retention of sulfobromophthalein were the most useful and least subject to equivocation in interpretation. On the whole there was remarkably close agreement between the results of any given series of tests and the clinical impression gained by a study of the patient at the time the tests were performed. Multiple tests of liver function appeared to have their greatest usefulness in the late stages of recovery from hepatitis when it was no longer possible to ascertain clinically whether convalescence was complete. At this stage of the disease the greatest degree of dissociation among the results of the various tests was observed.

In three groups of patients receiving supplements of methionine, choline and crude liver extract, respectively, and a diet high in protein and carbohydrate and moderately low in fat, no evidence of an accelerated recovery was obtained over that of a control series receiving the diet alone.

Prompt hospitalization and relative freedom from activity appeared to be of paramount importance in speeding recovery from hepatitis.

While recrudescence amounting to well defined deterioration of the patient's clinical condition following beginning convalescence was rare, 18.5 per cent showed a mild to moderate recrudescence following a period of apparent clinical recovery. In 82 per cent of these cases the recrudescence occurred following a period of activity occasioned by a grant of liberty or temporary discharge from the hospital. All patients in this group showed an eventual relief of clinical symptoms and normal tests of hepatic function after an average period of twenty days' additional hospitalization.

MORPHOLOGIC CHANGES IN RED BLOOD CELL WITH IRON DEFICIENCY ANEMIA

STEVEN O. SCHWARTZ, M.D.
and
VLADIMIR C. FLOWERS, M.D.
Chicago

One of the most signal forward steps in the field of hematology is a recognition of the fact that the term "secondary anemia" must give way to a descriptive diagnosis which implies the etiologic component. Next to infection, iron deficiency is probably the most common cause of anemia. It is our purpose to point out certain characteristics of the blood as determined from the analysis of 628 cases of iron deficiency, in each of which bleeding, either alone or in combination with other factors, was responsible for the anemia. We have become particularly impressed with the progressive changes which take place in the red cells as the iron deficient state becomes more and more definite, and the correlation of these changes with the severity of iron deficiency and the degree of anemia. Another point of practical importance which became apparent as the study progressed was the independent rate of fall of hemoglobin and red cells, with the more important of these factors, the hemoglobin, receiving too little attention.

MATERIAL

The material in this report was based on a study of adult patients entering the Cook County Hospital. In each case known or occult bleeding was present, often complicated by inadequate intake of iron-containing foods. In no instance was dietary inadequacy alone responsible for the anemia. The sources of bleeding were the nose, esophageal varices, peptic ulcers, carcinoma of the stomach, cecum, rectum, bladder and uterus, uterine fibroids and other causes of menorrhagia and metrorrhagia, isolated cases of thrombocytopenic purpura and Osler's disease, and combinations of these factors. Deficient iron intake was due in many instances to ill advised ulcer regimens or the abstinence from meats because of real or purported hypertension. No case was included in the series in which the iron deficiency was unexplained or complicating factors, such as infections or metastases, were prominent. No peculiarities of pattern were demonstrable for the different sex, race or age groups.

METHODS

Red cell counts were done in the usual manner. Hemoglobin determinations were made with a photoelectric colorimeter so standardized that 15.6 Gm. equaled 100 per cent hemoglobin. The color index was obtained by dividing the percentage of hemoglobin by the percentage of red cells. Blood smears were prepared by a modification of the cover slip technic and stained with Wright's stain. Red cell abnormalities in the smears were correlated with the red cell count, hemoglobin and color index. All figures were subjected to statistical analysis for standard variation from the normal by the formula $\delta = \sqrt{\frac{\Sigma d^2}{n-1}}$. No values were found subject to elimination. The T value $\left(\frac{m^1 - m^2}{\sqrt{\frac{\delta_1^2}{n_1} + \frac{\delta_2^2}{n_2}}}\right)$ was in all instances in excess of 5.

COMMENT

Lemery and Geoffy (1713) were the first to demonstrate iron in blood ash, and Menghini (1746) is credited with the discovery that this iron can be increased by increasing the feeding of iron-containing foods Sydenham (1681) introduced iron into clinical medicine for the treatment of anemia, while Blaud (1831) emphasized the specific action of iron in chlorosis and recognized that iron preparations restored the coloring matter to the blood. Reduction of iron in the blood of chlorotics was first reported in 1832 by Fodisch, while Andral (1842) showed that iron therapy caused an increase in the red cell count in this disease.[1]

The characteristics of the red cells which accompany iron deficiency are so well known as to require only enumeration. These are microcytosis, hypochromia, poikilocytosis, low mean corpuscular volume, low mean corpuscular hemoglobin and low mean corpuscular hemoglobin saturation. The low color index, which is the single most valuable "index" when based on accurate red cell counts and hemoglobin determinations, has also been well popularized. The clinical significance of these changes have been dealt with more recently by Castle and Minot,[2] Heath and Patek,[3] Price-Jones [4] and Wintrobe,[5] while Parsons [6] has demonstrated the experimental corollary in the rat.

Notwithstanding the extensive clinical and experimental literature on the subject, nowhere has the correlation between the development of the anemia, the fall of the hemoglobin and the exhaustion of the iron stores been discussed.

Our awareness that a rather precise correlation existed between the length and severity of the bleeding, the consequent exhaustion of the stored iron of the body, and especially the reduction of hemoglobin, diminishing color index and the ultimate fall in red blood cells, came as a result of observing large numbers of patients with chronic bleeding. It has also become apparent that no significant fall in any of these (red cell count, hemoglobin or color index) will accompany chronic bleeding as long as the iron stores remain intact

Once the stored iron is exhausted, the negative iron balance first manifests itself in a diminution of hemoglobin and a concomitant fall in color index, since the red cell level remains unchanged. From here on the hemoglobin fall is almost linear, with the red cell fall constantly lagging behind and resulting in an ever decreasing color index. This divergence continues until the color index reaches about 0.5, at a hemoglobin level of 25 per cent (3.9 Gm.) and a red cell level of 2.5 million. Since this represents the lowest limit of the color index (Reimann's [7] "rule of the minimal color index") [8] any further fall in hemoglobin will be followed by a parallel fall in the red cell count.

Aided by a grant from the Wilson Laboratories, Chicago

Read by title at the 18th annual meeting of the Central Society for Clinical Research, Nov 2, 1945

Though this report deals exclusively with adults, our experience has shown no difference for children or infants.

[8] Occasionally a case is encountered in which the hemoglobin will fall as low as 50 per cent before there is any fall of the red cell level In these instances the parallel fall begins at whatever level the 0 5 color index is reached, thus maintaining the relationship described

Because of this red cell lag it is quite apparent that the red cell count is extremely misleading and is of very little value in estimating the actual degree of anemia—i. e., the oxygen carrying capacity of the blood.

It is not difficult to understand the increasing discrepancy between hemoglobin and red cell count as the iron deficiency progresses on a purely mechanical basis—the available hemoglobin must be spread out more thinly to the cells being formed—but the reason for the falling red cell count and the final fixation of the ratio is somewhat more complex in its development. As the iron deficient state becomes full blown and the "available" iron stores become exhausted there is a drain on the ordinarily "unavailable" iron of the tissues, most especially the epidermoid structures (resulting in the typical hair, nail, skin and mucous membrane changes). Concurrently there is an increasing "maturation arrest" of the developing normoblast in the marrow. At first this "maturation arrest" merely produces a "left shift" in erythropoiesis, but eventually fewer and fewer cells reach the point in maturation which enables them to be liberated from the marrow. Ultimately (at a point corresponding to about one-half saturation of the cell with hemoglobin or color index 0.5) the iron deficiency increases to such a degree that not only is hemoglobin synthesis interfered with but nuclear maturation also becomes retarded and apparently even the formation of the cell stroma is impossible.

Along with the series of events outlined there occur specific morphologic changes in the red cell which, to a remarkable degree, parallel the falling color index. In normal blood or in well compensated bleeding the diameter, surface area, thickness, volume and hemoglobin contents are normal. With a fall of the color index to 0 9 the whole cell shrinks but for unit volume maintains its normal hemoglobin content. The cell is thus slightly microcytic. At color index 0.8 the cell has become still smaller and appears distinctly microcytic, with an accentuation of the central pale area due to increased thinness. At color index 0.7 the central pale zone is quite apparent, making the cell hypochromic; but its surface area is not reduced further. At color index 0.6 the hypochromia is quite evident, the majority of cells are very small, though considerable variation in size occurs, and occasional larger cells are present. Elongated cells and cells of bizarre shape appear in greater and greater numbers. At a color index of 0.5 (and the occasional lower levels[9]) the changes have reached their extreme. Poikilocytosis, microcytosis and hypochromia are the outstanding features of the cell, and though anisocytosis is also present it is not much in evidence since no significant numbers of large cells are found. In this range the cell appears to be little but a ring of hemoglobin. This picture is unmistakable and is pathognomonic of a severe "iron deficient state."

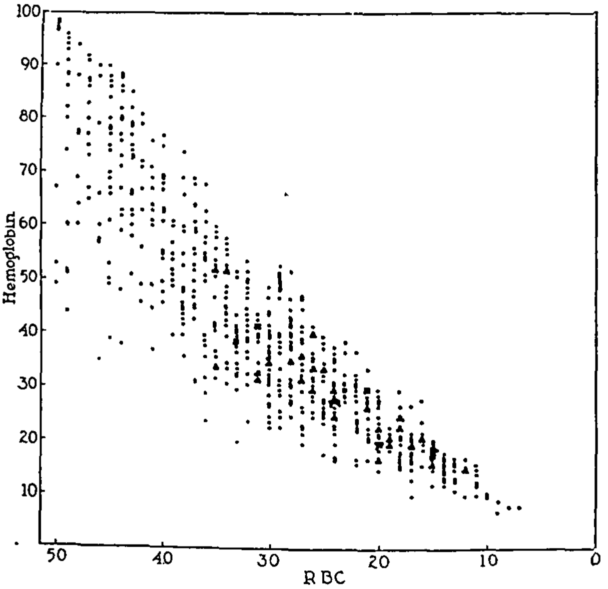

Fig 1 —Scatter curve, showing distribution of cases with hemoglobins plotted against red blood cells There is a close correlation between the anticipated and actual scattering of the cases

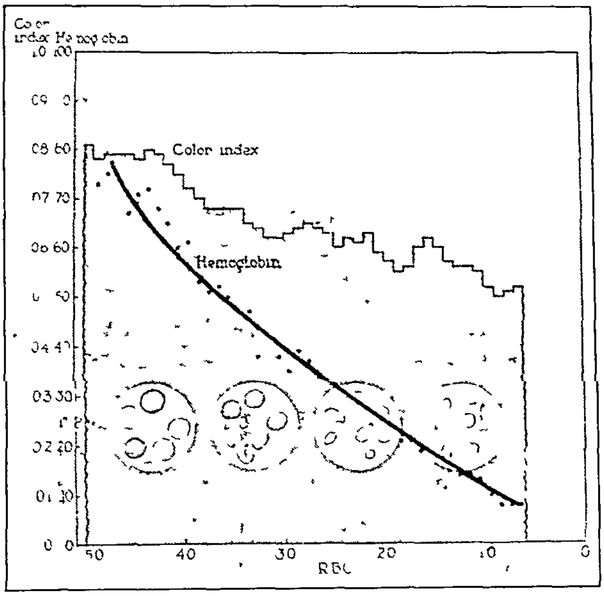

Fig 2 —Progressive fall in color index with diminishing hemoglobin due to iron deficiency The morphologic changes accompanying the diminishing color index are portrayed in the insets

In the development of this picture we have at first simply a readjustment of the cell envelop to the diminished hemoglobin available to it (microcytosis, reduced mean corpuscular volume). The cell envelop is unable to shrink beyond a certain point and therefore the available hemoglobin is less densely distributed (hypochromia, lowered mean corpuscular hemoglobin concentration). Finally, owing to the extreme paucity of iron, the cells are improperly made and the changes in size and shape become prominent (anisocytosis, poikilocytosis).

As the scatter curve indicates (fig. 1), the majority of cases comply rather closely with the expected pattern, but a considerable number fall above and below. The reason for this lies largely in the extreme heterogeneity of the group under analysis. It is obvious that the factors of cardiovascular age, rate of blood loss and protein nutrition alone will be enough to influence the scatter curves appreciably.

The findings herein described have even greater practical than theoretical implications.[10] The mere recogni-

---

[9] The color index may fall to a lower level occasionally. In our series the lowest color index observed was 0 35.

[10] Knowing either the hemoglobin or the red cell count, one may calculate the expected color index in the iron deficient state from the following formulas, provided the red cell count is 2.5 million and the hemoglobin 25 per cent (3 9 Gm) or over

$$\text{Color index} = \text{RBC (in millions)} \times 0\,2$$

$$\text{Color index} = \frac{\sqrt{\text{Hgb }\%}}{10}$$

tion that the anemia is of the iron deficient type immediately suggests etiology, a program of diagnostic approach, treatment and prognosis. Perhaps most important of these is the recognition that the iron deficiency (as such) can be simply, rapidly and economically treated, since it responds specifically to the administration of peroral iron. From the diagnostic standpoint, not only may one know that a negative iron balance exists, but any deviation from the described red blood cell to hemoglobin relation may be interpreted as implying a complicating factor or factors. It should be noted parenthetically that "pure" iron deficiency would undoubtedly show a much more precise correlation than that seen in the scatter curve had our cases been selected so as to eliminate all added factors which accompanied the bleeding, such as tissue breakdown or infections.

CONCLUSIONS

1. The development of the anemia of iron deficiency is characterized by

(a) A linear fall in the hemoglobin.

(b) A fall in red blood cell count which lags behind the hemoglobin fall and results in:

(c) A progressive diminution in color index.

2. At a hemoglobin level of about 25 per cent (3.9 Gm.) the color index reaches its minimum (about 0.5) and from here on the fall in hemoglobin and the fall in red cells parallel each other.

3. Characteristic morphologic changes occur in the red blood cells with the falling color index. These appear in the following order: microcytosis, hypochromia, anisocytosis and poikilocytosis.

4. The exact knowledge of red cells to hemoglobin relationship is invaluable in the analysis of anemias.

5. The recognition of the "iron deficient" type of anemia is important because it casts etiologic, therapeutic and prognostic light on the underlying disease.

6. In evaluating the type of anemia and in assaying its physiologic severity the accurate determination of the hemoglobin outranks the importance of the red cell count.

Conditions of Behavior.—There are three types of conditions of behavior: environmental (including, of course, the social environment), physiological and psychological. It is obvious that if personality is to be sought among the conditions of behavior and if personality is to be regarded as something psychological, then it must be sought among the conditions of the third type. This statement should, of course, not be taken to mean that environmental and physiological factors do not condition personality. If, however, personality is one of the conditions of behavior, then environmental and physiological factors condition personality and, thereby, condition behavior in two ways: directly, and indirectly, through the role they play in the development and subsequent alteration of the personality which, having developed, becomes an additional conditioner of behavior. Not to minimize the complexity of the situation, we must not overlook the fact that the physiological factors which condition personality are themselves conditioned by the environment and that the organism undoubtedly plays an important role in conditioning the environment. We may pursue our studies as far as we like, but for the descriptive study of personality, if the term is to be psychologically meaningful, we must look to those conditions of behavior which are psychological in character.—Chein, Isidor: Personality and Typology, in Twentieth Century Psychology, New York, Philosophical Library, 1946.

FAT AND SUGAR INTOLERANCE AS CAUSE OF GASTROINTESTINAL SYMPTOMS

LOUIS TUFT, M.D., and HENRY J. TUMEN, M.D.
Philadelphia

Patients with long-continued gastrointestinal symptoms, such as flatulence, belching, heartburn, abdominal pain or discomfort and diarrhea, have always presented difficult problems to the practitioner. The treatment of these patients is often unsuccessful because the cause of such symptoms remains undiscovered. After prolonged and detailed diagnostic studies have failed to demonstrate the presence of significant organic disease, the physician frequently labels the disorder as one that is "functional" in origin. This term, however, is used in a sense that is largely negative—to indicate that there is no demonstrable organic disorder of the gastrointestinal tract. Since this designation is applied to patients with such varied disturbance, one hopes that we soon will understand more fully just what factors produce the "dysfunction" in individual patients. Recently attention has been focused on the emotional and psychic disturbance that may cause gastrointestinal symptoms, and adequate psychotherapy may be successful in relieving those patients who require it. Frequently, however, therapy is limited to rather routine dietary restriction, the use of sedative and antispasmodic drugs and attempts at reassurance. Like all general and nonspecific therapeutic programs, this one often fails.

Some years ago, and particularly since the publication of the studies of Rowe, Vaughan and others, attention was directed to the fact that some of the so-called functional gastrointestinal disturbances are due to sensitivity to certain foods. Although this often amounts to a specific allergy, this need not be the case. As Alvarez noted, many foods provoke digestive symptoms because their physical or chemical characteristics cause difficulty in their digestion. Such foods as onions, cucumbers and radishes, to name but a few, are notorious in this respect. The digestive symptoms which follow the ingestion of these foods are usually nonspecific or nonimmunologic and do not depend on any specific allergic mechanism. They are instances of what we prefer to consider food intolerance rather than specific food allergy. The bloating, heartburn and abdominal discomfort which occur after eating moderate amounts of such substances as radishes, cucumbers or sauerkraut are probably not allergic in origin since they are common to a great many individuals, most of whom are free of digestive symptoms if ordinary dietary precautions are observed. On the other hand, if a patient develops vomiting or diarrhea or severe abdominal pain after eating such foods as milk, eggs or wheat—foods which most of us eat with impunity and which are ordinarily considered to be easily digested—it is reasonable to conclude that a specific allergy to those foods is present. In fact, it is the occurrence of such abnormal reactions after partaking of small amounts of foods that usually cause no reaction, which is most characteristic of true food allergy.

Because it is not always easy to differentiate between food allergy and food intolerance, a difficult diagnostic problem often arises. This is true for the allergist as well as for the general practitioner. If the patient is known to have other allergy disorders and if the suspected foods are those which are ordinarily easily digested, diagnosis may be relatively simple. If, however, the patient is not known to be allergic and if symptoms are caused by a food which has a reputation for distressing many individuals, it may be quite difficult to decide whether a true allergy exists.

Skin tests, unfortunately, do not always provide the hoped for diagnostic assistance, even if the more sensitive intracutaneous technic is used. There is often no agreement between the reaction given by the patient's skin and that given by his gastrointestinal tract to the introduction of the food in question. On the other hand, a detailed history and a study of the time relationship between the ingestion of foods and the development of symptoms offers a most valuable guide. For this purpose an accurate food diary is most helpful. Elimination diets and diet trials are invaluable in the study of this problem. They are time consuming and require careful control. If properly and faithfully used, however, they often supply the missing link in the chain of diagnostic evidence. Whatever the mechanism responsible for the digestive symptoms, whether this is true allergy or simply a food intolerance, removal of the offending substance from the diet should be carried out in attempting to relieve the patient's symptoms.

For some time we have been interested in the problems of food allergy and food intolerance and have had occasion to study them in many patients. During the course of our investigations our attention has been focused on a type of food disagreement which it has been difficult to classify as allergic. We refer to the patients who develop various gastrointestinal symptoms after ingesting fats or sugars, substances not ordinarily regarded as allergens. We have thought it best to describe these as intolerances to fats and sugars, although it is possible that subsequent studies may show these to be true allergies.

Because of the scarcity of reports on this subject we feel justified in calling attention to it. The nature of the problem is best indicated by description of some of the cases in which it has been encountered.

REPORT OF CASES

Case 1.—A man aged 40 had had gastrointestinal symptoms for approximately twenty years. They consisted of epigastric discomfort, belching, heartburn, abdominal soreness and cramps. These had been associated with numerous attacks of diarrhea, during which frequent mucoid and watery stools were passed. Repeated and detailed diagnostic studies, including gastrointestinal and gallbladder x-rays, had revealed no abnormality other than an irritable colon. Treatment had consisted of the usual bland diet and the liberal use of sedatives and belladonna derivatives, with occasional opiates. Although these drugs were useful in controlling distress, the patient was seldom free from the symptoms, which recurred year after year. Diarrhea was particularly troublesome, and for long periods no formed stools were passed.

After numerous investigations it was finally discovered that the patient was sensitive to milk and that taking of even the minute quantities which might be used in cooking other foods would cause abdominal cramps and diarrhea. Although skin tests with milk were negative, the fact that a milk allergy existed was substantiated by clinical trial and by the demonstration of similar sensitivity to milk in other members of his family. It was also discovered that the patient was sensitive to chocolate and to tomatoes. When all of these foods were removed from the diet, symptoms were reduced somewhat although by no means eliminated.

In 1941 the patient had a particularly severe and prolonged attack of abdominal pain and diarrhea. Despite what seemed to be an adequate diet he began to lose weight, the loss finally amounting to 25 pounds (11 Kg.). In an attempt to regain the weight the caloric intake was increased by substantially increasing the quantities of fat and sugar in the diet. For some time prior to this the patient had observed that partaking of large amounts of fats—such as salad oils, fried foods and fat meats—had caused gastric upsets, although lean meats could be taken without difficulty. When large amounts of fats were added to the diet there were violent recurrences of diarrhea. Such substances as egg yolk, butter and the fat of beef could not be tolerated, although small amounts of peanut or coconut oil caused no distress. The ingestion of sugar also induced diarrhea. On one occasion the taking of B-lactose caused severe intestinal symptoms, diarrhea and burning of the anus. Sugar used as candy or in stewed fruits was observed to precipitate additional attacks.

After a great deal of personal experimentation had convinced the patient of his intolerance to fats and sugars, these were eliminated from the diet, except for small amounts of butter. Since goat's milk caused no distress, this was substituted for cow's milk, and saccharin was used instead of sugar. The change in diet was followed by a striking change. Epigastric discomfort, heartburn and eructations disappeared. Abdominal cramps and diarrhea ceased, and for the first time in twenty years the patient passed formed stools; even constipation existed at times. He lost a feeling of malaise and fatigue that had previously been quite annoying and also began to regain some weight. At present his general condition is remarkably improved. Gastric symptoms are negligible, and intestinal upsets occur only after dietary indiscretions. The ingestion of fat and sugars must still be restricted, and when these are taken in appreciable quantities distress recurs. It is to be emphasized, however, that although he cannot eat the fat of chicken, beef or ham, the meats themselves can be taken in large amounts if the fat is removed. It has also been observed that even after a long period of good health a violent attack of diarrhea can be induced by the ingestion of sugar.

Case 2.—A man aged 42 had suffered with recurring attacks of abdominal pain, flatulence and diarrhea for almost as long as he could remember. These symptoms varied in severity but rarely disappeared for more than an occasional period of one or two days. From time to time extremely severe and prostrating attacks of diarrhea occurred. In addition the patient suffered with occasional migraine headaches. There was no history of hay fever or asthma. The family history was negative for allergic diseases. As a result of personal observation the patient had discovered that the ingestion of certain foods, notably milk, tomatoes and fish, was regularly followed by more severe symptoms.

Detailed studies of the gastrointestinal system, including x-rays, various laboratory procedures and sigmoidoscopy, revealed no evidence of organic disease. By means of elimination diets it was found that the patient was sensitive to milk and cheese, eggs, certain fish and peas. Removal of these from the diet was followed by definite subsidence of the gastrointestinal symptoms and disappearance of the headaches. The patient did not obtain complete relief of his diarrhea, however, and even when avoiding the aforementioned foods and consuming only those which experience had indicated should be tolerated he suffered recurring attacks. After further experimentation with diets it was observed that diarrhea followed the ingestion of fats and that the eating of fats—butter, meat fats and egg yolk—would precipitate looseness of the bowels. When fats were avoided the patient was able to eat all foods except the specific allergens mentioned and to remain symptom free. At present, on no other therapy except observance of his diet he continues without any diarrhea.

Case 3.—A man aged 35 had suffered attacks of diarrhea for about twenty years. The diarrhea had occurred for long periods without remission and had been associated with severe abdominal pain, with flatulence and also with belching and epigastric discomfort. Over a period of time the patient had noted some relation of his symptoms to the use of certain foods and had gradually eliminated milk, chicken, eggs and oranges from his diet. There was no family history of allergic diseases, and the patient did not suffer with hay fever, asthma or hives. Repeated studies by numerous physicians had failed to demonstrate the presence of any organic disease of the gastrointestinal tract.

The patient was subjected to an intensive survey and detailed studies of the gastrointestinal tract were carried out. Nothing of significance was demonstrated, although the barium enema revealed moderate irritability and spasm of the colon, and on sigmoidoscopy some excess of clear mucus was found. Complete allergy studies were then performed. By elimination diets and careful use of food diaries, sensitivity to milk, eggs, chicken, orange, tomato, beets and corn was found. When the use of these was discontinued there was definite decrease in symptoms. It was soon discovered, however, that sporadic and apparently causeless attacks of diarrhea occurred even when all known allergens were avoided. After further diet experimentation the patient became aware of the relation between these attacks and his use of fat and sugar. A meal that contained fish was tolerated if the fish was not fried. Eating of fried fish, however, was followed by diarrhea. The same was true of meat. A tiny amount of butter could be taken, but the use of large amounts always induced abdominal cramps and a loose movement. Sugar was found to cause diarrhea if added to tea or coffee, and large amounts of hard candy could not be tolerated.

After a great deal of trial the patient's food tolerances were determined. The allergens mentioned must be avoided, but all other foods, except more than the smallest amounts of fats and sugars, can be taken without ill affect. Very tiny amounts of butter can be used, and a little sugar can be used in the cooking of fruits; but if these restrictions are not observed diarrhea recurs. It has also been noted that the sensitivity to fats is not restricted to specific fats. When other fats, such as soy bean oil or peanut oil, were tried in an attempt to increase caloric intake, the tolerance for these was found to be just as limited as the tolerance for butter fat.

Case 4.—A man aged 37 was studied originally in 1939 because of allergic rhinitis and so-called sinus headaches. The family history revealed asthma in one brother and late hay fever in another. Complete intracutaneous skin tests revealed sensitivity to house dust, feathers, orris root and many foods. Elimination or avoidance of the offending allergens plus dust desensitization was followed by excellent results, so that at the end of a year desensitization was discontinued.

The patient returned in April 1943 because of recurring migraine headaches, which were becoming increasingly frequent, and also such gastrointestinal symptoms as dyspepsia and occasional diarrhea. He then stated that for many years he had been subject to these symptoms. He had been studied by a gastroenterologist, but no organic disease was found. A tentative diagnosis of "cholecystitis" was made and a low fat diet advised.

As part of the allergic study the patient was placed on a trial diet which was also low in fats and sugars. He was also given histamine injections. The headaches decreased in frequency and severity and his general condition improved. Gastrointestinal symptoms diminished greatly and he became free from indigestion. Diarrhea disappeared. The patient then recalled that he had never been able to tolerate fatty foods or fats in general but stated that this had always been attributed to his "gallbladder condition." When he tried eating fats again symptoms recurred—even the eating of eggs caused distress, presumably from the yolks, because egg white could be used freely. Since avoiding fats he has had few gastrointestinal symptoms or none. He was able to take sugar in any desired quantity, however, and in his case no sugar intolerance was ever noted.

Case 5.—A woman aged 42 for approximately fifteen years had had recurrent attacks of diarrhea, usually associated with abdominal cramps. Repeated intensive studies had never revealed organic disease of the bowel. Because of the presence of a good bit of nervous tension, a diagnosis of irritable colon of neurogenic origin had been made. The patient came from a family of which various members suffered allergic disturbances. She herself had had hives after taking chocolate and fish and also had had mild angioneurotic edema of unknown origin. She suspected that the ingestion of certain foods—fish, chocolate, excessive coffee and orange—caused diarrhea.

Incomplete skin tests showed sensitivity to chocolate, tomato and spinach. On elimination trial diets improvement occurred, but subsequent additions were not continued long enough to determine definitely foods which were not tolerated. It was found, however, that the ingestion of fats and sugars frequently provoked flatulence and diarrhea and that reducing them often brought an improvement. One event may be described as illustrating the effect of sugar ingestion: while on vacation and at a time when no food had been taken for a number of hours, the patient ate some candy which was made of pure maple sugar; within one hour violent diarrhea occurred. Similar episodes were also recalled by the patient, who has since observed that eating concentrated sweets of any type frequently has a laxative effect, inducing watery bowel movements.

COMMENT

These few cases illustrate the type of clinical picture which apparently arises from intolerance to fats and sugars, and the histories are similar to those of a number of other patients studied by us. The symptoms may be gastric, intestinal or both. The gastric symptoms include fulness and distress, belching, eructations and heartburn after eating, which are usually known collectively as "indigestion." Because these symptoms develop after fat ingestion, the presence of gallbladder disease is often suspected even though there may be no objective evidence of this.

The intestinal symptoms usually consist of flatulence, cramp-like pains and bowel irregularities, chiefly attacks of diarrhea. The movements are watery or contain excessive mucus. In our patients diarrhea has generally been the most striking complaint and, because no organic bowel disease had been found to explain this, the majority of the patients had been considered to have "irritable colon" or "mucous colitis."

We believe that definite intolerance to fats and/or to sugars was responsible for the symptoms of these patients because of the relief which followed elimination of these substances from the diet or their reduction to extremely small quantities. The intolerance to these substances seems to be generic and not restricted to single fats or sugars. In patients who were sugar sensitive any sugar—cane, malt or dextrose—produced diarrhea, and symptoms even followed the intake of large amounts of starchy food. Fat intolerance was also manifested indiscriminately toward all fats such as butter, vegetable oils, egg yolk and the animal fats taken with fat meats. Difficulty in digestion of the latter class of fats explains why patients could eat a large amount of lean meats such as ham or beef if it was boiled or baked but could not eat the same meats if fried or prepared with the fat retained. The same patient might tolerate white meat of stewed or roast chicken but might have distress after eating fried chicken or even the dark meat of the fowl.

The question of the tolerance of these patients for fats and sugars is, of course, partially a quantitative one. It is almost impossible to maintain a diet which is completely free of fats or sugars. These patients were able to handle the amounts of these substances present in what might be called "invisible quantities" in their foods. Usually, however, they experienced difficulty when the fats and sugars were taken in more than minimal appreciable quantities.

It should be observed that all the patients whom we have encountered with either fat or sugar intolerance have had definite allergies to other foods. Since the number of patients described is small and since many of the patients were referred specifically for allergy surveys, this fact may merely be coincidental. We are sure that those symptoms will be encountered in persons who can be shown not to suffer with allergy. The large number of patients who claim not to tolerate fatty and fried foods—and who are often erroneously considered to have gallbladder disease—probably includes many who have the form of fat intolerance described here.

Certain aspects of the intolerance to fats and sugars argue against this being due to allergy as this term is generally defined. There is first the fact that no patient was encountered who was intolerant to only one specific fat or sugar. The intolerance seems to be directed against entire classes of these substances, so that it was impossible, for example, to substitute vegetable fats for butter or dextrose for sucrose. It has also been noted that the patients usually were able to eat the protein portions of meat or chicken or egg but could not digest these proteins if they were not separated from the fats naturally associated with them. Since it is generally believed that allergic reactions are developed only against proteins, it would seem that some other explanation must be found to explain these adverse reactions to nonprotein substances.

At present we have no satisfactory explanation for the intolerance to fats and sugars observed in these and other patients. The digestion and absorption of fats is a relatively complicated process. It depends on the presence in the bowel of adequate quantities of bile acids and of pancreatic and intestinal enzymes, and on the ability of the intestinal mucosa to absorb the fatty acids and glycerol, which are the end products of fat digestion. The digestion of sugars is a much simpler process, consisting largely of conversion of polysaccharides to monosaccharides and the absorption of these.

It seems probable that the patients who suffer with fat and/or sugar intolerance have some defect in their ability to absorb these substances. This is suggested by the absence of any demonstrable pancreatic or biliary defect and by the fact that in most instances intolerance for both fats and sugars occurred in the same individual. The absorption of fats and sugars alike is dependent on a process known as phosphorylation—combination with phosphates for transportation across the mucosal barrier of the intestinal wall. These patients, therefore, may have some disturbance which interferes with phosphorylation so that absorption of both fats and sugars is inadequate. If unabsorbed sugar and fatty acids are permitted to accumulate in the bowel, symptoms may develop quite promptly. The sugars not only undergo fermentation with consequent gas formation but also have a hydrophilic and therefore a laxative effect. The undigested fats also act as intestinal irritants both because of the bulk of accumulated fat and because of the local mucosal action of the fatty acids.

CONCLUSIONS

A group of patients had numerous gastrointestinal symptoms, presumably the result of intolerance to fats and sugars. The symptoms consisted of epigastric fulness, belching, eructations, abdominal pain and bowel irregularities, notably diarrhea.

These symptoms were encountered in patients who were known to have food allergies, but we are of the opinion that the symptoms noted were due to "intolerance" to fats and sugars rather than to allergy in the ordinary sense.

Although the mechanism of the intolerance to these foods is not understood, some defect in their absorption probably exists.

Intolerance to fats and sugars may be a more frequent cause of gastrointestinal symptoms than is usually suspected.

PROLONGING THE EFFECTS OF PENICILLIN BY CHILLING

LIEUTENANT COMMANDER MAX TRUMPER, H(S), U.S.N.R.
and
COMMANDER GERSHOM J. THOMPSON, MC(S), U.S.N.R.

The virtues of a new curative substance are quickly broadcast; its limitations are examined later at more leisure. The ephemeral power of penicillin has set clinicians and scientists working on methods of prolonging its effective action, aiming to make unnecessary the renewal of intramuscular doses every few hours. Effective and prolonged blood levels have been obtained by using a penicillin beeswax-peanut oil mixture.[1] We have approached the problem from a different angle, using a simple method of chilling the area of injection [2] in order to retard the absorption of the penicillin by slowing the circulation around the site of the injection. For evaluating effectiveness of a new technic like chilling, it was decided to make the tests in gonorrhea cases, both because these were available and because they afford a good basis for study owing to the uniformity of the infection and the reliable criteria as to cure.

EFFECTS OF CHILLING ON CIRCULATION

The velocity of nearly all biologic processes, including those of sensation, varies directly with the temperature. Barcroft and Edholm [3] measured by means of a plethysmograph the blood flow in the human forearm after the limb had been placed in a constant temperature water bath for two hours. "The point at which the temperature was measured was about 1 inch below the skin covering the brachioradial muscle not far from the middle of the forearm." The temperatures employed ranged from 13 to 45 C. In all, seventy experiments were carried out on 5 normal men aged 25 to 40. They found that the average forearm blood flow ranged from 0.5 cc. per hundred cubic centimeters per minute at 13 C. to a speed of 5.9 cc. per hundred cubic centimeters per minute at 37 C. (cubic centimeters per hundred cubic centimeters arm volume per minute).

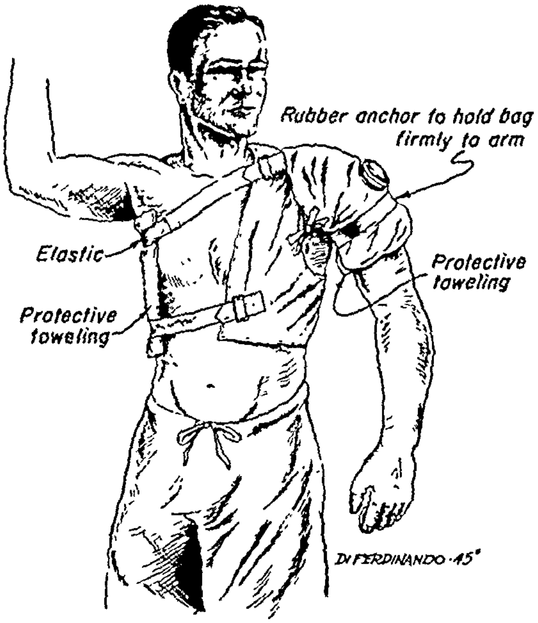
[3] Barcroft, H., and Edholm, O. G.: The Effect of Temperature on Blood Flow and Deep Temperature in the Human Forearm, J. Physiol. **102:** 5 (June 30) 1943.

This principle of the effect of temperature on body processes underlies the refrigeration methods used in surgery to create anesthesia for amputation cases.[4] The exact degree of coldness, however, best suited to insure both absence of sensation and safety from tissue trauma has not been agreed on, so that arbitrary standards still prevail.[5]

For our chilling technic we made, by means of a thermocouple, studies of the muscle temperature of 18 patients and found that by maintaining an ice bag around the upper shoulder for two hours the mean temperature in the deltoid muscle ½ inch below the skin was 17.3 C. (63 F.). This was sufficiently cold to insure absence of sensory function, obviating the pain of injection, and to retard the high rate of absorption of the pencillin, yet it afforded a wide margin of safety from danger of tissue trauma by freezing.

In order to learn the rate at which the muscle temperature returned to normal, a series of readings were then taken, commencing two minutes after removal of the ice bag and continuing every two minutes for one hour. The first reading showed the average temperature of the deltoid muscle ½ inch below the skin in the 18 cases to be 17.3 C. At the end of one hour the temperature averaged 29.5 C., which is equivalent to a rise in temperature of 1 degree C. every five minutes. Two additional cases under the same conditions showed temperatures so different from the other 18 cases that they have been grouped separately. In these 2 cases the temperature obtained two minutes after removal of the ice bag averaged only 24.5 C., and at the end of one hour the temperature averaged 35 C., which is equivalent to a rise of 1 degree every 5⅔ minutes.



Equipment for tests.

EQUIPMENT

The equipment used for the tests consisted of a circular ice bag of about 80 ounce capacity containing crushed ice and held in place by a supporting harness.[2]

Later this harness was replaced by a half vest, to which the ice bag was fastened by a cloth holder snapped on to the vest so that it could be removed readily. The vest was held in place by two belts, and an elastic strap fastened the ice bag holder securely to the upper arm, and two small tapes tied the holder to the vest, as illustrated in the accompanying sketch.

TECHNIC

The chilling procedure may be summarized by the following directions which were issued to ward personnel:

1. Two hours prior to the injection of penicillin, fill the ice bag 90 per cent full of crushed ice.
2. Before closing the bag squeeze out all excess air and repeat one hour later, so that the bag can be molded around the deltoid muscle.
3. Enclose the ice bag in the shoulder bag and place on the upper arm and shoulder, fasten it to the vest in the position indicated in the sketch and see that it is maintained there for two hours.
4. Chill the bottle of penicillin (100,000 units in 10 cc. of saline solution) in crushed ice for at least five minutes prior to the injection.
5. With a ½ inch hypodermic needle in a cool syringe, inject the chilled penicillin slowly into the deltoid muscle.
6. Replace the ice bag immediately and maintain it around the deltoid area for twelve hours, renewing the ice every few hours as needed.

CRITERIA FOR CURE

If both the smear and the culture of the prostatic secretion obtained forty-eight hours after the cessation of the urethral discharge were negative, the patient was considered cured. He was kept under observation, however, for a few additional days.

Clinical Results.—Three groups of patients, classified according to the dosage given, yielded the results in cures and failures given in the table after a single injection of penicillin according to the chilling technic.

Group A.—The potency of the penicillin undoubtedly affected the results. The first 15 patients, all treated with the same batch of penicillin, were cured. The next 7 patients were treated with the same dosage of a different batch of penicillin. Five of these 7 were not cured. Assays of penicillin used for these 7 patients showed it to be of reduced potency.

Group B.—Of the 35 patients treated with 70,000 units, 5 were those whose treatment with 50,000 had failed to effect a cure. Of these, 3 were cured when the dosage of 70,000 was administered. The remaining 2 were each treated with a total of 140,000 units in seven injections at two and one-half hour intervals. This resulted in 1 cure and 1 failure. The patient who was not cured when treated with first 50,000, then 70,000 and later 140,000 units for a gonorrheal infection was also being treated with oxophenarsine hydrochloride (mapharsen) and a bismuth compound for syphilis. He was finally given 2.4 million units of penicillin for the treatment of the syphilitic infection, which cured his gonorrhea.

All failures in group B were cured with the 140,000 units in seven injections at two and one-half hour intervals.

Group C.—Of the 4 failures in this group of 43 patients (each given 100,000 units) all were cured by retreatment with 140,000 units administered in seven injections at two and one-half hour intervals.

COMMENT

The effectiveness of penicillin has proved so remarkable that we are just beginning to learn of its limitations. To date there have been relatively few reports emphasizing penicillin failures. Bloomfield, Kirby and Armstrong[6] in such a study stressed the fact that "in studying a new therapeutic agent it is necessary not only to discover the conditions in which it is effective but also to determine the circumstances under which it fails or at least yields unsatisfactory results." Therefore we have studied those cases which failed to be cured by the lower dosage. Our experience has been that the potency of the penicillin, the resistance of the patient and the duration of the infection prior to treatment are all important factors. Therefore the dosage of 100,000 units, but preferably 140,000 or 150,000 units, is needed to cover all the variations involved. The wide variations in potency have been observed previously by investigators with extensive clinical experience. This variation has been attributed by one of us[7] to the inexact methods of assay. Sternberg and Turner[8] reported that their dosage schedules were only approximate, because assays were subject to an error of plus and minus 25 per cent. They state that in two hospitals certain lots of the drug resulted in a 50 per cent failure at the 50,000 unit schedule of treatment. On the other hand, only 9 per cent failures were obtained in 137 cases treated with 40,000 units of penicillin. These observations were confirmed and extended by Riba, Schmidlapp and Bosworth,[9] who reported 23.6 per cent failures in 233 gonorrheal patients that had received 50,000 units (10,000 every three hours). Of these 55 failures, 48 were retreated successfully with 100,000 units (10,000 every three hours).

In a study such as this, the selection of controls is always difficult. The military hospital must attempt to return all patients to duty as quickly as possible, and one cannot therefore compare effective therapy with ineffective therapy on alternate patients. A recent report on the effect of gonorrhea of a single injection of 100,000 units of penicillin in aqueous solution has been published.[10] Of 58 cases so treated only 24 were cured, that is 58.6 per cent failed. One small series in which the penicillin was mixed with globin or albumin[7] and injected as a single dose of 100,000 units showed that 45 per cent failed.

The 100,000 unit dose seems to be the minimal amount which, when administered in divided dosage or in single injection when mixed with beeswax and peanut oil, or in single injection with the chilling technic can be relied on to cover variations in potency and resistance to infection and to yield 90 per cent cures in uncomplicated gonorrhea. With the recent abundant production of penicillin and its lowered cost, together with the wide margin of safety as to its toxicity, the need for minimal dosage no longer exists except for purposes of studying the mechanisms of its activity and the incidence of relapses or recurrent infections. To attain cures of 95 per cent or more a larger dosage is required, 140,000 or 150,000 units intramuscularly within fifteen hours.[11] The maximum dosage used in our present studies on uncomplicated gonorrhea was 140,000 units (seven injections at two and one-half hour intervals), which proved successful in all the retreated cases in which it was used. Thus, no examples of penicillin fastness were observed.

In studying our failures with the 50,000 unit dosage, a factor appeared which, if confirmed by a larger number of cases, may prove significant. That factor is the duration of the infection prior to treatment and the role of the defense mechanisms of the body in enabling the penicillin to effect a cure.

The 5 patients who failed to be cured with 50,000 units had, when admitted, a urethral discharge on the average of one and seven-tenths days' duration and their white blood cell counts averaged 7,090. The patients who were cured with 50,000 units had when admitted a urethral discharge on the average of six days' duration and their white blood cell counts averaged 9,760.

In the group of patients treated with 70,000 units the duration of the discharge of the 5 who failed also averaged one and seven-tenths days, in contrast to seven days' duration in those cases that were cured. The differences in white blood cell counts were not significant.

Results in Three Groups of Patients

Group	Penicillin Dosage, Units	Patients Treated, Number	Patients Cured, Number	Patients Failed, Number	Patients Failed, per Cent
A	50,000	22	17	5	22.7
B	70,000	35	30	5	14.3
C	100,000	43	39	4	9.3

In the group of patients treated with 100,000 units, the duration of the urethral discharge of the 4 who failed averaged one and seven-tenths days; that of the cured cases averaged three and three-tenths days. The differences in white blood cell counts were not significant.

The theory that in uncomplicated cases the longer the duration of the infection prior to treatment the easier it is to obtain a cure is borne out only by groups given borderline dosage. Since the higher dosage cured irrespective of the duration of the infection or the height of the white blood cell count, it obscured the role of the body's defense mechanisms.

From our limited experience in this study it seems probable that a duration of the infection of at least six to seven days is a factor in determining the percentage of cures by penicillin therapy with borderline dosage, but that its role is difficult to ascertain when using dosages of 100,000 units or more.

This experience is in accord with that of sulfonamide therapy in gonorrhea. Long and Bliss[12] in their monograph on sulfonamide drugs present a number of reports in which the rate of cure in simple gonorrhea was always higher in the chronic than in the acute infection. They observed a definitely greater incidence of relapse in individuals whose infections were treated on the first to the seventh day of the infection in contrast to those whose infections were eight or more days old. Cokkinis and McElligott[13] advanced the theory that, the longer treatment is delayed, the more chance there is for the body to acquire immunity and to dispose of the organisms arrested by sulfanilamide. Support of this is provided by the complement fixation test, which rarely becomes positive before the second week.[12]

Various investigators[14] have reported that sulfonamide resistant gonorrhea can be effectively treated with penicillin in relatively small dosage. This can be attributed either to the greater potency of the penicillin used or to the fact that the duration of the infection had progressed to the point where antibodies were being produced in quantities sufficient to be an influential factor in determining the response to therapy.

Our views are in accord with the opinion expressed by Florey and Jennings[15] that "the good effects of penicillin depend on simultaneous action by the leukocytes and other defense mechanisms of the body which deal with the bacteria while multiplication is held in check by the penicillin."

SUMMARY AND CONCLUSIONS

One hundred patients with uncomplicated gonococcic urethritis were treated with a single dose of from 50,000 to 100,000 units of penicillin dissolved in saline solution and injected into the deltoid muscle, which was chilled before and after the injection.

Results from dosages of 50,000 and of 70,000 units gave cures of 77.3 per cent and 85.7 per cent respectively.

The 100,000 unit dosage cured 91 per cent of the patients. This percentage compares favorably with the results obtained by others using multiple injections as well as the single injection of 100,000 units of penicillin in mixtures of beeswax and peanut oil.

It can be concluded from the high percentage of cures that the chilling technic prolonged the effective action of penicillin, reduced to one the number of injections required to treat uncomplicated gonorrhea and rendered that injection painless, all of which was accomplished without introducing any other foreign substance intramuscularly.

Food Inspection.—The principles of good food preservation are very simple. They depend on the facts that: 1. Food spoilage is due largely to bacterial action. Thus, bacterial control results in food preservation. 2. Bacteria require certain favorable conditions for development. In general, they require (*a*) a suitable —usually warm—temperature, (*b*) moisture, (*c*) protein food and (*d*) a favorable medium for growth. For example, a high concentration of salt or sugar will check the growth of many bacteria.—Smillie, Wilson G.: Preventive Medicine and Public Health, New York, Macmillan Company, 1946.

TUBERCULOSIS AND ANAL FISTULA

RAYMOND J. JACKMAN, M.D.
and
LOUIS A. BUIE, M.D.
Rochester, Minn.

In 1939, together with Smith, we[1] reported a study of 206 consecutive patients who had anal fistulas and we considered the part tuberculosis plays in the disease. Since that time we have had the opportunity to study a larger series of patients and these, together with the 206 previously studied, compose the 600 patients on whom this report is based.

Opinions have varied widely as to the percentage of anal fistulas that are tuberculous and as to the part tuberculosis plays in anal fistulas. There are two reasons for the variance of opinion. The first is that the criteria on which the diagnosis is made differ. At one extreme are those who make demonstration of the tubercle bacillus in the fistula a requisite for positive diagnosis. At the other extreme are those who feel that the clinical picture, or even the demonstration of tuberculosis elsewhere in the body, is enough to establish the diagnosis of a tuberculous fistula. The second reason for the variance of opinion is the difference in the source of the material investigated. For example, figures or percentages from a tuberculosis sanatorium would be different from those from an institution in which the treatment of tuberculous patients is not the primary interest.

METHODS OF DETERMINING THE TUBERCULOUS OR NONTUBERCULOUS NATURE OF AN ANAL ABSCESS OR FISTULA

Inspection.—Many writers and investigators have felt that a tuberculous abscess or fistula has certain peculiar characteristics which make clinical diagnosis possible. It is not our purpose in this discussion to go into these characteristics. In our experience conclusions drawn from such a study, if lacking in scientific corroboration, have been of little value.

Guinea Pig Inoculation.—Some workers, particularly Martin and Sweany[2] and Fansler,[3] have questioned the reliability of guinea pig inoculation as a means of determining the tuberculous nature of anal fistulas. The reasons that can be offered against reliability of the method are the following: 1. It may yield a false positive. That is, the cause of the fistula may not be tuberculosis, yet micro-organisms of tuberculosis may have entered the fistula through its enteric opening. 2. It may yield a false negative. That is, the cause of the fistula may be tuberculosis, yet viable bacilli may not have been injected into the guinea pig or, having been injected, on rare occasions may not have been in sufficient number to give rise to tuberculosis in the body of the animal. Feldman and Magath,[4] however, on the basis of vast experience, have expressed the opinion that guinea pig inoculation warrants confidence in its reliability as a means of designating the tuberculous nature of clinical material.

From the Section on Proctology, Mayo Clinic.

[3] Fansler, W. A.: The Relationship of Tuberculosis to Fistula in Ano, J. A. M. A. **85:** 671-673 (Aug. 29) 1925.

[4] Feldman, W. H., and Magath, T. B.: The Reliability of Guinea Pig Inoculation in the Diagnosis of Tuberculosis, Am. Rev. Tuberc. **24:** 312-325 (Sept.) 1931.

Therefore it will be considered here that a negative result of guinea pig inoculation is dependable but, as shown by Martin and Sweany, that a positive result in a tuberculous patient with positive sputum is subject to error because fecal contamination may have occurred.

Histopathologic Examination. — McDonald[5] stated that the histologic picture of tuberculosis is definitive if the typical picture is seen. This picture will not be described here. The errors in histopathologic diagnosis of tuberculosis are those of inadequate sampling and, as Sweany[6] stated, the adequacy of the sampling depends on the experience of the one who takes the specimen. He stated that if samples are carefully and repeatedly taken, and if serial sections are made and carefully studied, the histologic diagnosis rarely will be erroneous. The laborious procedure of making and studying serial sections is a discouraging task when a relatively simple procedure such as guinea pig inoculation is available.

Combination of Clinical and Histologic Examination and Guinea Pig Inoculation.—In the examination to find whether a fistula is tuberculous or nontuberculous, clinical aspects, histologic examination and guinea pig inoculation all should be taken into consideration. If a specimen of fistula is taken from a patient who has pulmonary tuberculosis, possibly that fistula is tuberculous, but if guinea pig inoculation and further microscopic studies give negative results it should be considered nontuberculous. These three factors were considered in this study. Each of the findings was evaluated and compared with the other two.

TABLE 1.—*Results of Primary Study*

	Cases		Evidence			
Group	Number	Per Cent of 600	Clinical	Roentgenologic	Histologic	Guinea Pig
1	478	79.6	Negative	Negative	Negative	Negative
	49	8.2	Childhood Ghon	Negative	Negative	Negative
	527	87.8				
2	21	3.5	Positive	Positive	Positive	Positive
3	19	3.2	Positive	Positive	Negative	Negative
4	18	3.0	Positive	Positive	Negative	Positive
5	9	1.5	Negative	Negative	Negative	Positive
6	6	1.0	Negative	Negative	Positive	Negative
Total	600	100.0				

MATERIAL AND METHOD

It is emphasized that the patients included in this study presented the variety of complaints encountered in general practice. Including the 206 cases which formed the basis of our report, made with Smith in 1939, 618 consecutive cases in which operation was performed for anal fistula came under consideration. Before surgical operation each patient underwent physical examination, and routine studies of the blood and urine were performed. In addition to this, a roentgenogram of the thorax of each patient was made. Also sigmoidoscopy and, if indicated, other special studies, such as examinations of sputum, were carried out. At the time of the operation the surgeon took particular care to dissect out the fistulous tract. Half was sent for gross and microscopic examination; for the latter, from two to five sections were stained with hematoxylin and eosin. The other half was used for guinea pig inoculation.

The foregoing procedure could not be followed in full in 18 cases and they were eliminated from the study. Thus 600 cases remained for complete and successful study.

RESULTS

The results of the investigation are presented in the accompanying tables, of which table 1 is concerned with the primary study. Therein it will be noted that cases of group 1 were negative in all respects, for we consider that if the only evidence of tuberculosis found in a given case consists of a healed, childhood type of lesion, or a Ghon primary complex, the findings are, to all intents and purposes, negative. In group 2 all evidence was recorded as positive. In group 3 results of histologic examination and guinea pig inoculation were negative whereas clinical and roentgenologic evidence was positive. However, it is generally agreed that a tuberculous lesion of the lungs may coexist with a nontuberculous anal fistula. Therefore, concerning groups 1, 2 and 3, no particular questions arise.

TABLE 2.—*Results of Histologic Reexamination (the Restudy)*

	Cases		Diagnosis	
Group	Number*	Per Cent of 600	Reversed to	Remained
4	12	2.0	Positive	
	6	1.0	....	Negative
5	6	1.0	Positive	
	3	0.5	....	Negative
6	4	0.7	Negative	
	2	0.3	Questionable (called positive)	

However, in groups 4, 5 and 6, results of histologic examination and guinea pig inoculation did not agree and questions do arise. In group 4 did guinea pig inoculation give a false positive result or were insufficient sections studied microscopically? In group 5 were we dealing with a primary tuberculous fistula; did guinea pig inoculation give a false positive result; were lesions overlooked in histologic or, for that matter, in clinical, examination? In group 6 was the histologic evidence correct and all other evidence deficient?

TABLE 3.—*Results of Combining Tables 1 and 2*

	Cases		Evidence			
Group	Number	Per Cent of 600	Clinical	Roentgenologic	Histologic	Guinea Pig
1	531*	88.5	Negative	Negative	Negative	Negative
2	33†	5.5	Positive	Positive	Positive	Positive
3	19	3.2	Positive	Positive	Negative	Negative
4	6	1.0	Positive	Positive	Negative	Positive
5	3	0.5	Negative	Negative	Negative	Positive
6	2	0.3	Negative	Negative	Positive	Negative
7‡	6	1.0	Negative	Negative	Positive	Positive
Total	600	100.0				

* The included new cases were histologic negatives derived on reexamination from group 6 of table 1. See explanation in text.

† The included new cases were histologic positives derived on reexamination from group 4 of table 1. See explanation in text.

‡ This new group was formed when, on reexamination, reversal of the histologic diagnosis in 6 cases of group 5 of table 1 required their removal from that group. See explanation in text.

In view of these questions, Drs. A. C. Broders and J. R. McDonald of the Division of Surgical Pathology made histologic reexamination of the material representing these groups. In many instances the reexamination necessitated the making of serial sections stained with hematoxylin and eosin and, when still further examination was necessary, by the Ziehl-Neelsen method or the auramine technic. This resulted in reversal of the histologic diagnosis in two thirds of the cases of each of the groups 4, 5 and 6 (table 2). The restudy demonstrated the importance of examining many sections of fistulous tissue to determine its tuberculous or nontuberculous nature.

---

[6] Sweany, H. C., quoted by Martin, C. L., in Goldberg, Benjamin: Clinical Tuberculosis, Philadelphia, F. A. Davis Company, 1942, vol. 2, pp. 1149-1150.

On the basis of results of the restudy, the quantities recorded in table 1 were modified and table 3 resulted. The redistribution, which allowed table 3 to be formed from table 1, took place in the following ways: On restudy, reversal of the histologic diagnosis in 4 cases of group 6 caused these cases to conform to the all negative pattern of the original group 1 (table 1); therefore, in the redistribution, these 4 cases were added to group 1 (table 3). Also, on restudy, reversal of the histologic diagnosis in 12 cases of group 4 caused these cases to conform to the all positive pattern of the original group 2 (table 1); therefore, in the redistribution, these 12 cases were added to group 2 (table 3). However, reversal on restudy of the histologic diagnosis in 6 cases of group 5 did not cause these cases to conform to any of the original patterns (table 1) and, in the redistribution, group 7 came into being (table 3). It is evident that, on restudy, the incidence of agreement between the results of histologic examination and guinea pig inoculation was increased.

COMMENT

From the foregoing report of the primary and subsequent study, certain questions can be answered with a fair likelihood of the answers being accurate.

1. Should the presence of an anal fistula arouse the suspicion that pulmonary tuberculosis or a tuberculous focus is present in the body? Our study of 600 cases in which anal fistulas were present indicates that in a majority (88.5 per cent) there was no tuberculosis, either in the fistulas or elsewhere in the body, while in 11.5 per cent evidence of tuberculosis was found somewhere in the body. This figure of 11.5 per cent is sufficiently high to enable one to answer the foregoing question in the affirmative.

2. Is the tubercle bacillus a primary or a secondary invader of an anal fistula? In 3 cases, or 0.5 per cent (table 3, group 5), inoculation of a guinea pig with material from a fistula gave a positive result; in 2 cases, or 0.3 per cent (table 3, group 6), results of histologic examination only of the fistula were positive, and in 6 cases, or 1 per cent (table 3, group 7), both gave a positive result; yet in these 11 cases no focus of tuberculosis could be found elsewhere. We are unable to explain this, but as nearly as we could determine in this small group the fistula was primarily tuberculous. Fundamentally, however, it is impossible to answer the foregoing question from this study, nor are we familiar with any method available to answer such a question conclusively.

3. What percentage of anal fistulas are tuberculous? Our study would indicate that a relatively small number (7 to 8 per cent) of anal fistulas are tuberculous and in nearly all instances (thirty-three out of thirty-nine) in which they are unmistakably tuberculous there is a focus elsewhere in the body. The rounded percentages given in the previous sentence are derived from table 3, wherein groups 2 and 7 represent unmistakably tuberculous fistulas (6.5 per cent) and groups 4, 5 and 6 represent fistulas concerning the tuberculous nature of which some question remains (1.8 per cent). The total of these two percentages is 8.3.

4. What is the most satisfactory method of determining the tuberculous or nontuberculous nature of an anal fistula? If the guinea pig inoculation is successfully carried out and the result is negative, further examination should not be necessary. If it is positive and the histologic examination does not reveal tuberculosis, the possibility has to be considered that the tissue injected into the guinea pig was contaminated.

DIABETIC NOCTURNAL DIARRHEA

E. PAUL SHERIDAN, M.D.
and
C. CABELL BAILEY, M.D.
Boston

Diarrhea in diabetic patients is always a troublesome and often a serious complication. Our purpose in this report is to describe a syndrome characterized by intermittent nocturnal diarrhea in patients with diabetes mellitus.

In 1936 Bargan, Bollman and Kepler[1] reported 2 cases in which a tentative diagnosis of "diarrhea of diabetes" was made and stated that no failure of pancreatic external secretion could be demonstrated. In their cases the administration of pancreatic extract did not correct the disorder. Joslin, Root, White and Marble[2] also have discussed the association of nocturnal diarrhea and diabetes. The first case of nocturnal diarrhea in this clinic occurred in 1912.

Forty patients with this complication who had hospital studies and follow-up observations were selected for this investigation. The characteristic symptomatology of this syndrome is intermittent nocturnal diarrhea consisting of brown watery stools in a patient with diabetes mellitus. The intermittent character of the diarrhea was a striking finding in 34 of the 40 cases, while nocturnal incontinence of feces occurred in 31 cases.

Following is a representative case:

A. H. S., a man aged 25, developed severe diabetes requiring 60 units of insulin daily in September 1929. His diabetes was poorly controlled from the start. In August 1935 he developed a nocturnal diarrhea of eight to ten watery stools which showed no gross blood, mucus or pus. A barium enema and an upper gastrointestinal x-ray revealed only hypermotility of the intestinal tract. Proctoscopy was negative.

The feces did not show evidence of parasites, and cultures did not reveal abnormal organisms. Microscopically only occasional fat droplets, a few undigested muscle fibers and a few starch granules were seen. No macroscopic blood was detected. Several benzidine tests varied from 0 to ++. A quantitative fat estimation of the stools for seventy-two hours revealed 1.4 per cent, or an average of 11 Gm. of fat in twenty-four hours. An Ewald test meal revealed no free hydrochloric acid, and the total acidity was 30 degrees. Examination of the duodenal contents revealed normal proteolytic, slightly reduced lipolytic and definitely reduced amolytic enzymes. Agglutination for typhoid, paratyphoid and dysentery organisms was negative.

From the George F. Baker Clinic, Elliott P. Joslin, medical director. Dr. Sheridan is Fellow in Medicine, George F. Baker Clinic. Dr. Bailey is Research Fellow in Medicine, Harvard Medical School, and physician, New England Deaconess Hospital.

[1] Bargan, J. A.; Bollman, J. L., and Kepler, E. J.: "Diarrhea of Diabetes" and Steatorrhea of Pancreatic Insufficiency, Proc. Staff Meet., Mayo Clin. 2:737 (Nov. 18) 1936.

[2] Joslin, E. P.; Root, H. F.; White, Priscilla, and Marble, Alexander: Treatment of Diabetes Mellitus, ed. 7, Philadelphia, Lea & Febiger, 1940, p. 465.

The patient was placed on a low residue diet and given dilute hydrochloric acid 60 drops daily, tincture of belladonna 30 drops daily and several costive drugs including bismuth (subcarbonate) and paregoric, all of which failed to relieve the diarrhea. Crude liver extract was then tried intramuscularly in 2 cc. daily doses with striking improvement and a reduction of the number of stools to only one or two daily.

The nocturnal character of this type of diarrhea is the most striking symptom. Patients frequently are troubled little or none at all during the day yet may have eight, ten or more stools at night. The stools in all cases were watery and unlike the frothy, bulky, odorous stools found in steatorrhea. Incontinence of feces during sleep is a most embarrassing feature.

The intermittent character of this diarrhea is also striking, and spontaneous remission is usually followed in a few days or weeks by a recurrence. The effectiveness of treatment is difficult to evaluate without follow-up studies because of this tendency to temporary spontaneous improvement.

Observations in Forty Cases

Case No.	Sex	Age at Onset of Diarrhea	Duration of Diabetes, Years	Total Insulin Dose, Units	Watery Nocturnal Diarrhea	Nocturnal Incontinence	Intermittent Character	Neuritis	Spinal Fluid Total Protein	Liver Extract Response

40	♂	34	7	35	Yes	Yes	....	Yes	65	Not given

DATA IN FORTY CASES

At the onset of the diarrhea the average age of the patient was 42 years, the ages ranging from 20 to 79 years. The average duration of diabetes was nine years. In this series there were 23 males and 17 females.

LABORATORY STUDIES

X-Rays.—Examination of the upper gastrointestinal tract in 17 cases revealed no abnormalities, although pancreatic calculi were found in 1 instance. Examination of the colon by barium enema was negative in 28 cases with the exception of increased spasticity observed in 6 cases. In the 15 cases studied by proctoscopy the mucosa was normal. A rectal examination in 38 cases was negative except for a relaxed anal sphincter in 5 patients.

Gastric Analysis.—Achlorhydria, even after histamine, was found in 14 of the 29 patients whose gastric contents were examined. The remaining 15 patients had free hydrochloric acid averaging 25 degrees. Achlorhydria has been estimated to occur in 30 to 40 per cent of all diabetic patients,[3] and Root [4] has emphasized that its frequency tends to increase with the duration of diabetes as well as with the age of the patient.

Spinal Fluid.—Eighteen cases were studied with spinal fluid determinations. The cell count in every case was found to be within normal limits. Seventeen of the 18 cases showed a definite elevation of the total protein averaging 88 mg. In one third of them (6 cases) the total protein was more than 100 mg. These findings suggest the presence of a neurogenic disturbance in the central nervous system.

Hematology.—The blood picture was remarkable in that 38 of the 40 patients had normal erythrocyte counts. The remaining 2 patients had red blood cell counts of 3,940,000 and 3,820,000. The hemoglobin content averaged 90.6 per cent. The blood Hinton test was negative in 39 cases and doubtful in 1. The hematology indicates that pernicious anemia and syphilis are not factors in the etiology of this condition.

Ocular Fundi.—Ophthalmologic examination in 33 cases revealed the presence of diabetic retinitis in 11, or one third of the total examined. In 1 case the retina could not be seen because of cataracts.

TREATMENT

Various therapeutic measures, including vitamins, chemotherapy (succinylsulfathiazole and sulfaguanidine), hydrochloric acid and drugs exerting a costive effect have proved of little or no value. A low residue, nonirritating diet is always prescribed but alone is not effective. It was found, however, that crude liver extract given parenterally was of definite value in controlling the diarrhea in 26 of the 28 cases in which it was used. Some patients discontinued this treatment a short time after returning home and a recurrence of the diarrhea followed, but when the liver extract was resumed the diarrhea again subsided. Although the tendency to spontaneous remission must be remembered in evaluating any treatment in this disorder, the response to liver extract is prompt and striking in most cases. The necessity of continuous liver extract treatment cannot be overemphasized. Two to four cc. of crude liver extract given intramuscularly daily for four to six days has proved effective and should be followed by weekly injections.

COMMENT

This syndrome of nocturnal diarrhea seems to be a specific complication of diabetes mellitus and as far as we can determine has not been reported in nondiabetic patients.

Previous poor diabetic control, as evidenced by hyperglycemia and glycosuria, was outstanding in each of the 40 cases and may act as an important etiologic factor.

Diabetic neuritis preceded the onset of the diarrhea in 58 per cent of the 40 cases reported, which suggested the possibility that the diarrhea syndrome may be a manifestation of diabetic neuropathy. Further, in 2 of these cases, in which eventually the neuritis was cured, the diabetic diarrhea completely disappeared. If this is the case one might suspect a disturbance of sympathetic innervation, since it has been shown[5] that these nerves exert an inhibiting action to the entire colon. Learmonth and Markowitz[6] have sectioned the colonic (sympathetic) nerve to the colon in dogs and demonstrated increased colonic activity. Rundles[7] recently pointed out that patients with diabetic neuropathy may develop unusual degrees of peripheral sympathetic nerve damage as revealed by sweating deficiencies, loss of vasomotor and pilomotor control, dependent edema and certain types of skin alterations. He further stresses the sympathetic nerve dysfunction in his report of orthostatic hypotension and orthostatic tachycardia in 5 patients with diabetic neuropathy. Rudy and Epstein[8] also have emphasized that diabetic neuritis is not limited exclusively to the peripheral nerves but involves the entire nervous system including the central, peripheral and autonomic parts, with an especial predilection for the peripheral nerves.

CONCLUSION

1. Nocturnal intermittent diarrhea is a distinct syndrome which may occur in patients with diabetes mellitus.
2. Evidence suggests that this condition may be a manifestation of diabetic neuropathy.
3. Crude liver extract parenterally offers the most effective symptomatic treatment.

Clinical Notes, Suggestions and New Instruments

GENERALIZED SUBCUTANEOUS EMPHYSEMA FOLLOWING RESECTION OF LARGE BOWEL

LOWELL BROWN, M.D., and J. WILLIAM HINTON, M.D.
New York

While generalized subcutaneous emphysema is not an infrequent clinical finding, it is an unusual occurrence following surgical operation on the large bowel. Only 2 similar cases have been reported in the literature.

REPORT OF CASE

S. A., a white man aged 47, entered the New York Post-Graduate Hospital Aug. 29, 1945 with a history of malaise, weight loss and increasing constipation of eight months' duration. Two attacks of crampy upper abdominal pain and distention led him to seek medical advice.

The patient was well developed, stocky and slightly obese. Except for slight pallor of the skin and mucous membrane and the presence of moderate tenderness in both upper quadrants of the abdomen, physical examination was negative. A barium colon enema showed an annular defect in the upper part of the descending colon.

Laboratory work-up revealed the red blood count to be 4.39 million with 11.3 Gm. of hemoglobin. The white blood cell count, urinalysis, blood chemistry and electrocardiogram were within normal limits. The erythrocyte sedimentation rate was 51 mm. in one hour.

The patient was prepared for resection with catharsis, colonic irrigations, whole blood transfusions, intravenous amigen and the administration of succinylsulfathiazole. After one week operation was performed. The abdomen was entered through a left rectus muscle splitting incision. One inch distal to the splenic flexure a large annular growth was encountered which was causing nearly complete obstruction. No metastases to liver or regional nodes were evident. The growth, together with a good portion of uninvolved bowel and a wedge of mesocolon, was resected and an aseptic end to end anastomosis performed using the Furniss clamp. Three layers of interrupted cotton sutures were used in making the anastomosis. Five Gm. of sulfanilamide powder was placed without drainage in the abdomen and the abdomen closed in anatomic layers with interrupted number 4 cotton for peritoneum, fascia and skin. The operation was made technically difficult by the patient's stocky, obese habitus, and complete reperitonealization of the left lumbar gutter was not possible.

The operative procedure was well tolerated, but beginning with the second postoperative day the course was stormy, with daily elevations of temperature to 103-104 F. and considerable abdominal pain and distention. On the third postoperative day the patient passed a number of loose stools and considerable flatus. Coupled with these signs of peritonitis he developed evidence of pulmonary consolidation, and full doses of intravenous sodium sulfadiazine and intramuscular penicillin were started, without, however, any noticeable change in the clinical picture.

On the evening of the eleventh postoperative day a grapefruit sized tumefaction suddenly appeared in the left pectoral region which palpation revealed to be a subcutaneous collection of gas. This was limited above by the clavicle, below by the costal margin, medially by the sternum and laterally by the anterior axillary line. The chest had been examined about an hour before, so that it was known definitely that there had been no change in auscultatory or percussion findings. The trachea was in the midline and there was no crepitus of face, neck or arms. The abdomen, however, was still distended and there was crepitus in the left flank just above the anterior superior spine. Nowhere was there any evidence of inflammation in the skin or subcutaneous tissues. Examination of the wound revealed that it was entirely normal. Within a few hours the emphysema had spread to the neck, face, arms and even down to the hands, giving the patient a grotesque Buddha-like appearance.

During the ensuing week his condition became progressively worse and he was irrational at times. On the eighteenth postoperative day the left flank, which for a day or so had seemed slightly inflamed, was noted to be red and indurated. Under pentothal sodium anesthesia, a 6 inch incision down to the transversalis fascia was made and packed wide open. No pus was encountered.

The following day, the distention still being considerable, paracentesis was carried out. When the peritoneum was entered in the epigastric region there was a sudden escape of much fecal smelling gas, with immediate collapse of the entire distended abdomen. Several ounces of thin tan colored fluid also was aspirated. A rubber catheter was inserted for continuous deflation, and 50,000 units of penicillin was instilled every two hours. Therapy with a specific bacteriophage was begun intravenously.

Two days later a fecal fistula developed in the midportion of the operative incision, and at the same time feces was obtained from the drainage tube in the epigastrium, which now communicated directly to the former. From this time on the patient's condition improved and by the twenty-fourth postoperative day he was passing flatus and small amounts of feces by rectum, and while his abdomen showed only moderate distention his facial emphysema had almost disappeared. He was able to leave the hospital on the seventy-fifth postoperative day. At present, six weeks following discharge, there is no drainage and his wound is nearly completely healed.

X-ray studies with contrast mediums prior to his discharge revealed multiple sinus tracts extending from the left iliac area to the epigastrium. Culture of the aspirated abdominal fluid showed nonhemolytic streptococci and Bacillus coli communior. Pathologic examination of the operative specimen revealed the tumor to be a papillary cystadenocarcinoma of the colon. The few lymph nodes in the specimen contained no tumor.

COMMENT

The most common origin of subcutaneous emphysema is known to be the chest and respiratory passages, where it may occur secondary to a lung injury or secondary to pneumothorax spontaneously or artificially produced. It may occur following tracheotomy and even occasionally following operation on the nasopharynx.

Less frequently subcutaneous emphysema originates within the abdomen. Here it may follow traumatic rupture of the hollow viscera or more rarely may occur secondary to spontaneous perforations. Several instances of subcutaneous emphysema accompanying perforated peptic ulcers have been collected by McCorkle and Stevenson,[1] who present an illustrative case together with a review of the literature. The manner in which gas reaches the subcutaneous tissues despite an intact peritoneum is discussed. Similarly a case of subcutaneous emphysema of the scrotum resulting from the perforation of a sigmoid diverticulum is reported by Rankin and Judd.[2]

Gas may also occur in the peritoneal cavity as the result of infection by gas producing organisms. The best example is found in cases of appendical abscess due to a gas forming colon bacillus. Review of the literature, however, revealed only 1 reported instance of subcutaneous emphysema in such a case.[3] This paper unfortunately is not available to us.

Subcutaneous emphysema also occurs, of course, in connection with infection of the subcutaneous tissues by any of the gas forming organisms.

Two cases similar to that being presented have been found in the literature. Baumecker[4] performed a side to side anastomosis between the ascending and the descending colon for inoperable carcinoma of the transverse colon. On the second postoperative day the patient developed emphysema of the abdominal wall, which subsequently spread upward into the neck and down as far as the thighs. On the fifth day postoperatively a fecal (?) fistula appeared, which closed spontaneously nine days later. There was never any elevation in temperature, and Baumecker concludes that the gas originated in a leakage of the anastomosis.

Von Hasselbach[4] records a case of subcutaneous emphysema arising after the performance of a colostomy. There was no evidence of infection, and he believes the gas originated directly from a perforation of the bowel by the needle in suturing.

Baumecker mentions another case in which slight subcutaneous emphysema occurred following laparotomy, due, he feels, to the postoperative leakage from the peritoneal cavity of air admitted at operation. Such leakage could occur, as he suggests, if intra-abdominal pressure was increased by straining or distention, especially if closure had been insecure. We have seen 1 such case in which crepitus was discovered in an apparently clean wound (cultures were negative) on the seventh postoperative day. A sudden temperature rise of obscure cause had occurred which was found at postmortem to be due to a fulminating hepatitis.

In the case herein reported there was obviously a leakage of the anastomosis. Whether the gas was produced by a gas forming colon bacillus in the course of a peritonitis caused by this organism, whether it came directly from the bowel lumen or whether both mechanisms played a part is not clear. We feel that the former explanation most nearly accounts for the clinical findings. The subsequent spread of gas was obviously made possible by the peritoneal defect left at operation.

130 East Seventy-Ninth Street.

VISUALIZATION OF OTITIC BRAIN ABSCESS WITH IODIZED OIL

EDWIN J. BLONDER, M.D.
Chicago

Delineation of an otogenic brain abscess by iodized oil is useful in determining the size and shape of the abscess; repeated use would prove an excellent guide to the progress of such an abscess under management.

Review of the effect of lipiodol on brain tissue[1] following lumbar myelography indicated that symptoms or findings the patient may have subsequently could not be related to the retention of the iodized oil in the brain. Evans[2] in 1944 reported the use of 2 cc. of iodized poppy seed oil in a right frontal lobe abscess instilled through a trephine opening. The roentgenogram revealed that the abscess had ruptured to the ventricle. His patient recovered under penicillin. Kahn[3] filled a chronic temporosphenoidal abscess cavity through a trephine with thorium dioxide and obtained a roentgenogram with good filling. Thorium dioxide particles are phagocytosed by cellular elements of the capsule, so that increase in the size of the abscess is indicated in the roentgenogram. Iodized oil on the contrary is not absorbed by the tissue, and in my patient the lipiodol was evacuated within one week, as indicated by the roentgenogram. Kopetzky and Almour[4] used lipiodol to follow fistulas in the petrous bone and in some instances spills were revealed in the cranial cavity. I have been unable to find any reports of an otitic brain abscess filled with an iodized oil through a mastoidectomy.

My patient had a chronic temporosphenoidal abscess that was uncovered following a radical mastoidectomy. One week after

the operation, about 15 cc. of undiluted lipiodol was instilled in the abscess cavity. Roentgenograms revealed a beautiful filling of the abscess cavity, as can be noted in the reproductions. The lipiodol was evacuated within one week through a large rubber drain, as indicated by subsequent roentgenograms. The patient was discharged from the hospital forty-four days after the operation and was found in good condition on a recent examination.

REPORT OF CASE

A man aged 37 entered the Illinois Eye and Ear Infirmary on June 6, 1943 with a history of bilateral suppurative otitis media since childhood. Shouted voice could not be heard at either concha. A right peripheral facial paralysis had been present for five years. No surgery had ever been performed on either ear. The patient consulted us because of a very severe right temporal pain which was not relieved by medication.

The right ear canal was dry; the drum was almost entirely destroyed, and the middle ear was filled with scar tissue and moist granulations. The left canal was moist, and the drum and middle ear were similar to the right. Spoken voice was not heard in either ear. General physical and neurologic examinations were negative except for the right peripheral facial paralysis The ophthalmologic service reported normal fundi and visual fields. A normal caloric response was obtained with irrigation of both ears with 50 per cent alcohol at 68 F. No spontaneous nystagmus or past pointing was present. The temperature was 98 F., pulse rate 88, respiratory rate 20. The blood count revealed 3,550,000 red cells, 9,900 white cells, polymorphonuclears 72 per cent, lymphocytes 22 per cent, monocytes 1 per cent, eosinophils 2 per cent, hemoglobin 71 per cent. The blood and spinal Wassermann reactions were negative. The roentgenologist reported bony sclerosis of both mastoids, with some absorption on the left, the side opposite the pain.

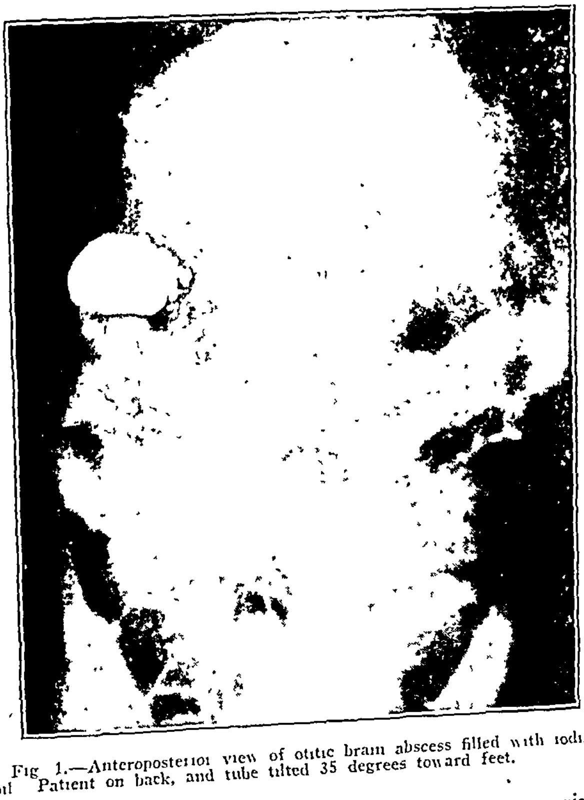

Fig 1.—Anteroposterior view of otitic brain abscess filled with iodized oil Patient on back, and tube tilted 35 degrees toward feet.

Because of the right facial paralysis and the severe right temporal pain in addition to the chronic ear suppuration, a right radical mastoidectomy was performed, followed by opening of the temperosphenoidal abscess through the roof of the attic. The mastoid was sclerotic except for the periantral region and the fistula to the abscess. The attic was cleared of granulations, and the fistula followed to the middle fossa. A sudden gush of brown liquefied pus indicated that the abscess had been reached. Gauze packed in the abscess opening slowed the evacuation of pus to reduce the danger of secondary edema of the brain tissue. A second pack was placed in the mastoid cavity. The wound was permitted to remain open. Sulfonamide therapy was instituted. The contents of the brain abscess were sterile on culture.

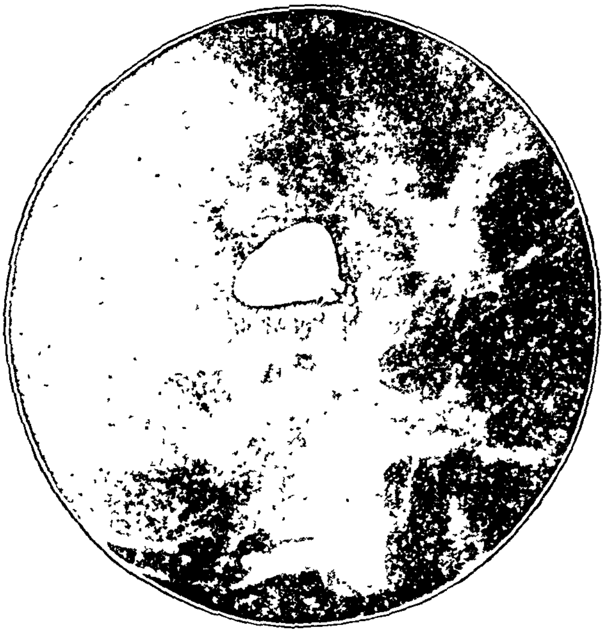

Fig 2.—Lateral view of otitic brain abscess filled with iodized oil. Note the sharp outline.

The abscess was again entered one week later with the patient under a hypnotic. Temperature was 100 F. Both packs were removed. A flexible probe indicated that the abscess cavity was large and had a firm capsule. About 15 cc. of undiluted lipiodol was instilled in the abscess cavity by means of a glass syringe and a silver eustachian catheter. No pressure was used. This procedure was performed on a cart in the operating room. The patient was wheeled immediately to the x-ray room for films. The results were beautiful, showing the abscess cavity well filled. A large soft rubber tube was inserted in the abscess cavity after the films were taken. Many subsequent films were taken to indicate the progress. The roentgenogram demonstrated that the lipiodol was completely evacuated in one week

The patient's temperature returned to normal five days after the lipiodol instillation Rubber drains were changed about every six days. Forty-four days after the operation the patient was discharged from the hospital and has been observed at frequent intervals since. He is a good lip reader and works at pressing clothes.

On March 1, 1945 a complete examination revealed the patient to be in excellent physical condition The ears were dry. No headaches had been present since his discharge from the infirmary. The otoneurologic examination revealed no evidence of a temporosphenoidal abscess. This was confirmed by additional examinations by our neurologist, our ophthalmologic service and a series of roentgenograms

CONCLUSIONS

1. Iodized oil is useful in outlining an established brain abscess.
2. The iodized oil may be of some therapeutic value in the management of an otogenic brain abscess.
3. The use of lipiodol is a safe procedure to use in an established otogenic temporosphenoidal abscess.

25 East Washington Street.

Council on Physical Medicine

The Council on Physical Medicine has authorized publication of the following reports. HOWARD A. CARTER, *Secretary.*

HOLMSPRAY ATOMIZER AND NEBULIZER ACCEPTABLE

Manufacturer: T. J. Holmes Co., Inc., Chartley, Mass.

The Holmspray Atomizer No. 605 is a device for applying medicaments to the nose and throat. It is an all glass atomizer adapted for spraying oils, aqueous solutions and alcoholic solutions, especially designed for disseminating compounds which affect metals or are affected by contact with metals. The device is equipped with a rubber bulb to create pressure and gives a direct, relatively heavy spray.

Holmspray Atomizer No. 605.

The Holmspray Nebulizer No. 630 is different from the Holmspray Atomizer in that it produces a finely disseminated, almost invisible vapor designed to reach more distant parts of the respiratory tract. Like the Atomizer, it is all glass and is designed for compounds which affect metals or are affected by contact with metals. It is equipped with a rubber bulb.

Holmspray Nebulizer No. 630.

The Council on Physical Medicine voted to accept the Holmspray Atomizer No. 605 and the Holmspray Nebulizer No. 630 for inclusion in its list of accepted devices.

BELTONE MONO-PAC HEARING AID ACCEPTABLE

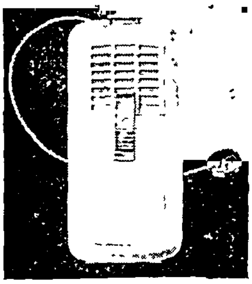
Manufacturer: Beltone Hearing Aid Company, 1450 W. 19th Street, Chicago 8.

The Beltone Mono-Pac Hearing Aid is a three tube instrument with transmitter, amplifier and batteries in one case. A single cord connected to an air conduction receiver is attached to the case.

Physical Dimensions:
- Case: 5½ by 2 9/16 by 1⅛ inches.
- Receiver: Either 1 inch diameter or ¾ inch diameter air conduction crystal (Brush).

Weight:
- Case (containing batteries, transmitter and amplifier): 11¼ ounces.

Current consumption:
- A battery (1½ volts), 60 milliamperes.
- B battery (30 volts), 0.68 milliampere.



Beltone Mono-Pac.

Current drain is independent of volume control setting.

Acoustical gain for pure tones:

	250	500	1,000	2,000	3,000	4,000	5,000 F
Maximum gain, high tone.....	26.5	37.0	49.0	55.0	51.0	37.5	22.0 decibels
Maximum gain, medium tone..	32.0	39.5	51.5	54.0	51.0	36 5	21.0 decibels
Maximum gain, low tone......	29.0	35.0	39.5	49.0	41.5	25.5	8.0 decibels

These values were obtained with the large size crystal receiver (1 inch diameter). The measurements were obtained with an artificial ear. The instrument was mounted on a body baffle. These values do not represent absolute sound pressure values but indicate the amplification efficiency of the hearing aid at the different frequency levels shown. These values are accurate to within plus or minus 3 decibels.

Physical and Mechanical Features: The entire instrument, including batteries, is contained in a single case of black plastic material, rectangular with rounded edges. The combined volume control and "off-on" switch consists of a round knob positioned in an inset at the top of the case. The case is somewhat larger and heavier than the conventional tube hearing aid transmitter and amplifier case, since it also contains the batteries. The total weight, however, is less than that of the conventional instrument which has separate cases for transmitter and batteries.

Performance: This instrument operates in an entirely satisfactory manner. There is a minimum of inherent amplifier, case and cord noise.

The Council on Physical Medicine voted to include in its list of accepted devices the Beltone Mono-Pac Vacuum Tube Hearing Aid.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN SMITH, M.D., *Secretary.*

PERCOMORPH LIVER OIL (See New and Nonofficial Remedies, 1945, p. 637).

The following additional dosage form has been accepted:

MEAD JOHNSON & COMPANY, EVANSVILLE, IND.

Oleum Percomorphum with Other Fish Liver Oils and Viosterol: 10 cc. bottles.

MANNITOL HEXANITRATE (See New and Nonofficial Remedies, 1945, p. 334).

The following dosage form has been accepted:

E. R. SQUIBB & SONS, NEW YORK

Tablets Mannitol Hexanitrate: 16 mg. and 32 mg.

GOLD SODIUM THIOSULFATE (See New and Nonofficial Remedies, 1945, p. 175).

The following additional dosage form has been accepted:

MERCK & CO., INC., RAHWAY, N. J.

Gold Sodium Thiosulfate: 75 mg. bottles.

THIAMINE HYDROCHLORIDE (See New and Nonofficial Remedies, 1945, p. 610).

The following additional dosage form has been accepted:

MEAD JOHNSON & COMPANY, EVANSVILLE, IND.

Tablets Thiamine Hydrochloride: 5 mg.

BACTERIAL VACCINE MADE FROM HEMOPHILUS PERTUSSIS (See THE JOURNAL, Jan. 5, 1946, p. 31).

The following dosage form has been accepted:

PARKE, DAVIS & CO., DETROIT

Pertussis Vaccine, Immunizing (Sauer): 6 cc. and 24 cc. vials. 15,000 million H. Pertussis per cubic centimeter.

RIBOFLAVIN (See New and Nonofficial Remedies, 1945, p. 614).

The following additional dosage form has been accepted:

ABBOTT LABORATORIES, NORTH CHICAGO, ILL.

Tablets Riboflavin: 10 mg.

SULFATHIAZOLE SODIUM (See New and Nonofficial Remedies, 1945, p. 213).

The following dosage form has been accepted:

ABBOTT LABORATORIES, NORTH CHICAGO, ILL.

Sterile Sodium Sulfathiazole Anhydrous: 5 Gm. ampuls.

ASCORBIC ACID (See New and Nonofficial Remedies, 1945, p. 622).

The following dosage form has been accepted:

MCKESSON & ROBBINS, INC., BRIDGEPORT, CONN.

Tablets Ascorbic Acid: 25 mg., 50 mg. and 100 mg.

SATURDAY, MARCH 9, 1946

BOMBING AND HEALTH

During the war opinion varied sharply as to whether or not air bombardment could reduce a nation such as Germany to the point of surrender. Many of the British felt continuance by Germany of its aerial bombardment of September 1940 for a few days longer would have forced Britain to give up. Germany received during the five years of war at least thirty times the weight of high explosives that the Luftwaffe was able to hurl on Britain, and yet surrender came only after formidable land-borne attacks of the United Nations' armored columns.

What effect, then, did air warfare have on the German people? One of the most revealing of all investigations made following V-E day was that of the U. S. Strategic Bombing Survey, which issued (and very promptly) a model report.[1] A team of American scientists, many of them physicians, followed the advancing Allied armies during the closing days of the war, assembling data from health authorities and viewing conditions before the dust of war was settled or the rubble cleared. Most striking was the fact that the health of the German people was not broken even though nearly half of their hospitals and other medical facilities had been destroyed. The state of affairs in the larger cities was hideous, and the most seasoned of the Wehrmacht troops insisted that they would prefer duty on an active battle front to exposure to heavy air bombardment of an industrial area.

The Survey estimates that about 500,000 people were killed during Allied air attacks, and probably four times that number were wounded. In Hamburg during a single month (July 1943) more than 50,000 people were killed, which is considerably more than twice the number of fatalities sustained in the London area throughout the whole war period. The incendiary raids were feared more than those of high explosives, and the cause of death in such raids was generally not burns but rather suffocation. It was estimated at Hamburg that the temperature in a burning block of dwelling houses rose to 1,500 degrees Fahrenheit. In these circumstances air raid shelters became living furnaces, and the frightened occupants frequently emerged naked only to find that they were enveloped on all sides by an even greater heat that quickly suffocated.

A number of disease entities rose sharply during the war period, particularly peptic ulcer, and coronary disease in the younger age groups. Psychiatric breaks were much less frequent than might have been anticipated, perhaps on account of the psychologic stability induced by propaganda. The German birth rate, which was on the increase up to 1939, fell progressively during the war years. Oddly enough, death from cerebral hemorrhage and diabetes decreased during the war years.

Repeated disruption of communications finally had its effect. In April 1945 Professor Karl Brandt, Reich Commissar for Military and Civilian Medicine and Health, informed Hitler that 20 per cent of all essential medical supplies had been destroyed, that 40 per cent of those in stock would not last two months and that the remainder could maintain the country for only four additional months. For his analysis of the situation Brandt was promptly put to death, Der Fuehrer regarding him as defeatist.

URINARY ACID

The body is inherently an acid producing organism. The chemical reaction from which the major portion of metabolic energy is derived, namely the oxidation of carbon, yields a potentially acid product, carbon dioxide. In addition, lactic, beta hydroxybutyric and acetoacetic acids are common side products of metabolism. Furthermore, certain foods, notably proteins and cereals, contribute to the acid produced in bodily economy; in this connection it has been estimated that from 30 to 80 milliequivalents is the magnitude of the excess of acid over base in our daily dietary. The mechanism whereby the acid-base balance is maintained within physiologic limits and the devices for ultimate removal of acid from the body have received much attention. The buffer systems in the blood and extravascular fluids are the first line of defense against a decrease in p_H; the lungs, kidney and skin are involved in the final elimination of acid from the organism. The urine is ordinarily considerably more acid than is the blood; one of the prime functions of the kidney is to excrete acid without the loss of equivalent amounts of base. This organ forms ammonia and substitutes it for base, in combination with the metabolic acids, returning the base to the blood. Also in the distal tubule changes in the phosphates occur which likewise tend to conserve base while metabolic acid is being removed in the urine.

A recent report[1] describes experiments designed to shed further light on the mechanism whereby the urine attains its final acidity in the distal renal tubule. Acidosis was induced in unanesthetized suitably trained laboratory animals, and by the use of data from concomitant blood and urine analyses the glomerular filtration rate was calculated and the total acidity of the urine determined. Under these conditions it was observed that the titratable acidity of the urine was greater than could be accounted for by the change in phosphates with reabsorption of the more alkaline form or by the action of carbonic acid on the phosphate with the reabsorption of bicarbonate. Indeed these two mechanisms accounted for only one fourth to one third of the total acid excreted. The Cornell investigators believe that the observed facts can be explained by a mechanism in which the renal tubular cells take an active part in ion exchange: the transfer of hydrogen ions from the peritubular blood to the urine in the lumen in the tubule and the return of sodium ions from the urine to the blood in the form of bicarbonate. The factor within the cell responsible for catalyzing part of this transfer is probably carbonic anhydrase; this enzyme combines carbon dioxide from the cell metabolism and from the postglomerular blood with water to form carbonic acid, which in turn provides the hydrogen ions for the exchange.

[1] Enloe, Cortez F., ed.: The Effect of Bombing on Health and Medical Care in Germany, Morale Division, U. S. Strategic Bombing Survey, War Dept., Washington, 1945.

[1] Pitts, R. F., and Alexander, R. S.: Am. J. Physiol. **144**: 239 (July) 1945.

The foregoing suggestions regarding the origin of the acidity of the urine are supported by convincing experimental evidence. A thorough understanding of all aspects of acid-base equilibrium and the factors and mechanisms involved is so important in modern medicine that further corroboration of these carefully considered views will be awaited with interest.

NATIONAL SCIENCE FOUNDATION

Two Senate subcommittees have joined in concurrent reports urging the establishment of a National Science Foundation and reporting on the new National Science bill, S. 1850, which has been perfected jointly by the two subcommittees. The perfected bill is the product of many hearings and conferences between scientists and the members of the subcommittees. The American Medical Association has already announced its support of the general purposes of this legislation, which is designed to permit continuation in the postwar period of the coordinated and intensified research that yielded such magnificent results during the war. The report emphasizes particularly the desirability of extending research in the basic sciences and of overcoming the deficit of competent young investigators in the natural sciences and engineering. Some of the wartime scientific developments, such as our increased knowledge of atomic energy and the development of radioactive isotopes of the common elements, should be helpful to chemists and physiologists in studying living tissues and disease.

Specifically, the report indicates that medical research should be aided, particularly in the investigation of heart disease, diseases of the blood vessels, tuberculosis, arthritis, and nervous and mental diseases. Also cited are the common cold and the aging process in man as areas in which research should be intensified. The subcommittee points out that the by-products of other scientific developments made during the war promise to accelerate medical research.

The report suggests that the Bureau of the Budget and the congressional Committees on Appropriations should approve separate budgets for each of the major divisions of the foundations. President Truman recommended $40,000,000 for the first fiscal year of the operation of the foundation in his 1946 budget message. This appropriation will probably be made when the bill passes, since the Office of Scientific Research and Development discontinues its activities in June. To the medical sciences will be allocated not less than 15 per cent of the funds appropriated for research and development activities.

In the revised measure the use of a full time staff and a part time scientific personnel is provided, the full time staff being charged with the actual administrative responsibilities and the part time staff of nongovernment scientists with the planning and evaluating of all programs of the foundation. In its organization the National Science Foundation is directed by an administrator who consults and advises with a National Science Board on all matters of major policy, program and budget. The board consists of nine members appointed by the President by and with the advice of the Senate from among persons who are especially qualified, plus the individual chairmen of the several divisional scientific committees. Each such scientific committee, as for instance the committee in the division of medical sciences, consists of not less than five and not more than fifteen members who are appointed by the administrator with the advice and approval of the board. These divisional scientific committees elect their own chairmen once they are established.

Among other divisions of the foundation is a division of publication and information to promote the widespread dissemination and utilization of scientific findings. Through this division the foundation is authorized to provide for complete publication together with financial and other assistance to nongovernment scientific journals, to provide aid in the work of translating and abstracting scientific publications and to aid other activities which will make scientific literature more readily accessible to working scientists and other users of scientific information.

The measure provides for the permanence of the National Roster of Scientific and Specialized Personnel. It recognizes the rights of private organizations to such research as they themselves finance. It provides also for strengthening international cooperation by assisting American scientists to participate in international scientific conferences and in the development of specific science projects.

Current Comment

SPECIFICITY OF THE KAHN REACTION

In a recent report McDermott [1] stated that the Kahn standard test has shown a consistent record of 100 per cent specificity in eleven consecutive evaluation studies on tests for syphilis conducted by the U. S. Public Health Service from 1937 to 1945. In these evaluation studies portions of the same "unknown" specimens of blood were submitted to different laboratories for serologic examination. The eleven evaluation studies included the examination of approximately 1,000 cases of tuberculosis, febrile diseases, cancer and other diseases, excluding malaria and leprosy, and slightly more than 1,000 normal persons, making a total of 2,022 cases. These results of the Kahn test should not be interpreted to mean that the test is 100 per cent specific under all conditions. Kahn's interest in perfecting a verification test for the detection of false positive reactions [2] is ample evidence that his test may also give such reactions. Thus, watchfulness is needed to detect false reactions in all seropositive cases in which no clinical or epidemiologic evidence points to syphilis.

DR. MARTHA M. ELIOT—PROPAGANDIST FOR THE CHILDREN'S BUREAU

From the Children's Bureau of the United States Department of Labor comes a newspaper release quoting Dr. Martha M. Eliot as urging a nationwide maternal and child health program because it will offer thousands of opportunities for professionally trained men and women. Of course it will also permit a tremendous expansion of the functions of the Children's Bureau and take away from fathers and mothers the personal responsibility and contacts with their own children that are significant in the American system of living. According to the release, Dr. Eliot said "We have come to accept the fact that the health of the nation's children is as much a public responsibility as their education." To support her propaganda Dr. Eliot cited some figures which are susceptible of misinterpretation; possibly these figures were cited in this manner so that they would be misinterpreted. "In one out of six counties," says Dr. Eliot, "there is only one doctor to 3,000 or more people. Under a good standard there would be one doctor available for every 750 people. In eighty-one counties there is no practicing physician." Dr. Eliot could have added that we had one doctor for every 750 people in the United States before the war but that the voluntary offering of their services by 60,000 physicians to the armed services changed the ratio. Since the United States is the only country in the world that ever had as many as one doctor to every 750 people one wonders on what basis her calculation of a good standard was reached. Dr. Eliot also estimates that we need 48,000 additional public health nurses to advise mothers in their homes about how to care for themselves and their children. She is much disturbed because three out of four counties have no regular monthly maternity clinic where mothers can learn how to prepare for safe childbearing. We were under the impression that the doctor who accepts the responsibility for giving obstetric care to a prospective mother is the proper person to inform her as to how to prepare for safe childbearing. Apparently the Children's Bureau feels that mothers should henceforth obtain this advice from regular monthly maternity clinics. Among the greatest menaces to the American democracy is the technic whereby the bureaucracies in Washington spend a considerable portion of their time and their funds in urging on the American people expansion of the funds and personnel allotted to those bureaucracies.

HOSPITAL PHARMACY

In the modern hospital pharmacy has an important place. Recently Shoemaker, in a discussion of the role of pharmacy in the modern hospital (The Role of Pharmacy in the Modern Hospital, William G. Shoemaker, American Professional Pharmacist, Vol. X, November 1944) emphasized the relationship between the physician and the pharmacist under close association in hospital life. After discussing principles, factors influencing the operation of the pharmacy, its purpose and its relation to the use of drugs, the pharmacy committee, records, files and the business office, he concludes that the advantages of a well supervised pharmacy "are greatly appreciated by those who benefit from and come in contact with the problems of medicine." He urges closer cooperation between the physician and the pharmacist in supplying quality drugs and making use of the newer therapeutic measures. The most progressive hospital pharmacies include proper organization and thorough understanding of the part which the pharmacy plays in hospital life. Hospital boards need to modernize and equip the hospital pharmacy properly. Such improvements yield economic and social benefits.

NEW JOURNAL ON BLOOD

A new bimonthly publication, *Blood*—The Journal of Hematology, has just appeared. The selection of William Dameshek as editor in chief, of George R. Minot as consulting editor and of a staff of associates and assistant editors composed of the representative hematologists of this country augurs well for its future. The first issue contains, among others, a contribution by Edwin J. Cohn on the composition, function and clinical uses of blood, a contribution by Charles A. Doan and Claude-Starr Wright on primary congenital and secondary acquired splenic panhematopenia and one by George R. Minot and his associates on differentiation of pernicious anemia and certain other macrocytic anemias by the distribution of red blood cell diameters. An American journal devoted exclusively to the problems of the diseases of the blood is sure to be received with enthusiasm.

NATIONAL HEALTH PROGRAM OF THE AMERICAN MEDICAL ASSOCIATION

Adopted by the Board of Trustees and the Council on Medical Service, Feb. 14, 1946

1. The American Medical Association urges a MINIMUM STANDARD OF NUTRITION, HOUSING, CLOTHING AND RECREATION as fundamental to good health and as an objective to be achieved in any suitable health program. The responsibility for attainment of this standard should be placed as far as possible on the individual, but the application of community effort, compatible with the maintenance of free enterprise, should be encouraged with governmental aid where needed.

2. The provision of PREVENTIVE MEDICAL SERVICES through professionally competent health departments with sufficient staff and equipment to meet community needs is recognized as essential in a health program. The principle of federal aid through provision of funds or personnel is recognized with the understanding that local areas shall control their own agencies as has been established in the field of education. Health departments should not assume the care of the sick as a function, since administration of medical care under such auspices tends to a deterioration in the quality of the service rendered. Medical care to those unable to provide for themselves is best administered by local and private agencies with the aid of public funds when needed. This program for national health should include the administration of MEDICAL CARE, INCLUDING HOSPITALIZATION TO ALL THOSE NEEDING IT BUT UNABLE TO PAY, such medical care to be provided preferably by a physician of the patient's choice with funds provided by local agencies with the assistance of federal funds when necessary.

3. The procedures established by modern medicine for advice to the prospective mother and for ADEQUATE CARE IN CHILDBIRTH should be made available to all at a price that they can afford to pay. When local funds are lacking for the care of those unable to pay, federal aid should be supplied with the funds administered through local or state agencies.

4. The child should have throughout infancy PROPER ATTENTION, INCLUDING SCIENTIFIC NUTRITION, IMMUNIZATION AGAINST PREVENTABLE DISEASE AND OTHER SERVICES INCLUDED IN INFANT WELFARE. Such services are best supplied by personal contact between the mother and the individual physician but may be provided through child care and infant welfare stations administered under local auspices with support by tax funds whenever the need can be shown.

5. The provision of HEALTH AND DIAGNOSTIC CENTERS AND HOSPITALS necessary to community needs is an essential of good medical care. Such facilities are preferably supplied by local agencies, including the community, church and trade agencies which have been responsible for the fine development of facilities for medical care in most American communities up to this time. Where such facilities are unavailable and cannot be supplied through local or state agencies, the federal government may aid, preferably under a plan which requires that the need be shown and that the community prove its ability to maintain such institutions once they are established (Hill-Burton bill).

6. A program for medical care within the American system of individual initiative and freedom of enterprise includes the establishment of VOLUNTARY NONPROFIT PREPAYMENT PLANS FOR THE COSTS OF HOSPITALIZATION (such as the Blue Cross plans) and VOLUNTARY NONPROFIT PREPAYMENT PLANS FOR MEDICAL CARE (such as those developed by many state and county medical societies). The principles of such insurance contracts should be acceptable to the Council on Medical Service of the American Medical Association and to the authoritative bodies of state medical associations. The evolution of voluntary prepayment insurance against the costs of sickness admits also the utilization of private sickness insurance plans which comply with state regulatory statutes and meet the standards of the Council on Medical Service of the American Medical Association.

7. A program for national health should include the administration of MEDICAL CARE, INCLUDING HOSPITALIZATION, TO ALL VETERANS, such medical care to be provided preferably by a physician of the veteran's choice, with payment by the Veterans Administration through a plan mutually agreed on between the state medical association and the Veterans Administration.

8. RESEARCH FOR THE ADVANCEMENT OF MEDICAL SCIENCE is fundamental in any national health program. The inclusion of medical research in a National Science Foundation, such as proposed in pending federal legislation, is endorsed.

9. The services rendered by VOLUNTEER PHILANTHROPIC HEALTH AGENCIES such as the American Cancer Society, the National Tuberculosis Association, the National Foundation for Infantile Paralysis, Inc., and by philanthropic agencies such as the Commonwealth Fund and the Rockefeller Foundation and similar bodies have been of vast benefit to the American people and are a natural outgrowth of the system of free enterprise and democracy that prevail in the United States. Their participation in a national health program should be encouraged, and the growth of such agencies when properly administered should be commended.

10. Fundamental to the promotion of the public health and alleviation of illness are WIDESPREAD EDUCATION IN THE FIELD OF HEALTH and the widest possible dissemination of information regarding the prevention of disease and its treatment by authoritative agencies. Health education should be considered a necessary function of all departments of public health, medical associations and school authorities.

MEDICINE AND THE WAR

ARMY

WOMEN'S ARMY CORPS MEMBERS URGED TO REMAIN IN SERVICE

The War Department recently announced a program to encourage members of the Women's Army Corps to remain in service beyond their date of eligibility for separation to meet the critical shortage of skilled personnel in army hospitals, personnel centers and headquarters installations. In a directive to commanders of installations in this country and overseas, the War Department urged them to make every effort to encourage WAC officers and enlisted women to remain in service. The directive said:

"Owing to the critical shortage of skilled personnel available, it is desired that every effort be made to encourage personnel of the WAC with usable skills to volunteer for retention in the service. There is a critical requirement for skilled personnel in personnel centers, hospitals and headquarters installations. WAC volunteers whose skills cannot be utilized by the service in which they are serving will be encouraged to volunteer for service in another force. WAC volunteers may indicate a desire for overseas service, and such assignment will be made if feasible. However, no definite commitment for overseas service for WAC personnel can be made at this time."

The War Department also announced provisions whereby honorably discharged former enlisted Wacs may seek reentry into the service. Certain conditions exist for reentry:

1. Volunteers for reentry into the service must submit application in writing to the Adjutant General, Washington, D. C.
2. Volunteers for reentry into the service must volunteer either for the duration of the war plus six months or until Sept. 30, 1946, unless sooner relieved for the convenience of the government.
3. Volunteers must be between the ages of 20 and 50 years.
4. Volunteers must waive all rights to discharge because of marital status or age.
5. Volunteers must possess a skill usable by the War Department or a major continental force.
6. Volunteers will be accepted in the grade held at the time of discharge.
7. The duty assignment will be as directed by the War Department.

NEW DIRECTOR OF SANITATION AND SANITARY ENGINEERING

Lieut. Col. John W. Regan, assistant director of the Sanitation and Sanitary Engineering Division, Preventive Medicine Service, was recently appointed director of that division, succeeding Col. William A. Hardenbergh. Colonel Regan graduated from Harvard Medical School, Boston, in 1936 and entered the regular army in 1940.

ARMY AWARDS AND COMMENDATIONS

Major Herman L. Taft

Major Herman L. Taft, formerly of North Bergen, N. J., was recently awarded the Bronze Star for meritorious achievement in operations against the enemy on Mindanao in the Philippines. An accompanying citation disclosed that Major Taft, during the period from April 27 to July 5, 1945, as chief of the orthopedic section in an evacuation hospital, "worked diligently and tirelessly to provide his patients with the best possible care. During this period it was necessary to expand the hospital 50 per cent above its normal capacity. Among the battle casualties were a great number of serious orthopedic cases. By his superior surgical ability, his exercise of good judgment and his painstaking and serious thought he produced excellent results, saving many lives and limbs and preventing permanent disabilities. The example set by this officer and the results of his efforts were an inspiration to all who came in contact with him. His service during the Mindanao operation reflects great credit on himself, his profession and the military service." Dr. Taft graduated from Columbia University College of Physicians and Surgeons, New York, in 1929 and entered the service Aug. 18, 1942.

Colonel George G. Durst

The Bronze Star was recently awarded to Col. George G. Durst, formerly of Greenwood, S. C., "for meritorious service in connection with military operations as chief surgeon, Ground Force Reinforcement Command, and medical adviser to commanding general, Ground Force Reinforcement Command, European Theater of Operations, from Nov. 17, 1943 to May 3, 1945. Colonel Durst demonstrated broad professional and military knowledge in disseminating policies and definition concerning physical standards to be followed in declaring personnel limited assignment. By his alertness and constant insistence on proper medical screening he made sure that reinforcements passing through this command were in top physical condition prior to assignment to combat units. Colonel Durst's outstanding performance and devotion to duty contributed materially to the success of the war effort and reflect great credit on himself and the armed forces of the United States." Dr. Durst graduated from the Medical College of the State of South Carolina, Charleston, in 1937 and entered the service Jan. 1, 1941.

Lieutenant Colonel Oscar Eugene Nadeau

The Legion of Merit was recently awarded to Lieut. Col. Oscar E. Nadeau, Chicago, for outstanding work as medical officer in charge of the Fletcher General Hospital, Cambridge, Ohio. The citation accompanying the award read: "Colonel Nadeau's professional capacity and administrative ability were evidenced by the efficiency and high standards with which the surgical section functioned when peak numbers of the sick and wounded were hospitalized. From the date of activation to the cessation of hostilities, there was no surgical death recorded at this hospital, an achievement symbolizing the skill, resourcefulness and high level of care Colonel Nadeau provided for patients at Fletcher General Hospital." Dr. Nadeau graduated from Rush Medical College, Chicago, in 1913 and entered the service Oct. 1, 1942.

Captain Granville W. Larimore

The Army Commendation Ribbon was recently presented to Capt. Granville W. Larimore, chief of the Health Education Unit, Preventive Medicine Service, Office of the Surgeon General, for his work on control of venereal diseases at the Army Air Forces Southeast Training Center, Maxwell Field, Alabama. Dr. Larimore graduated from Rush Medical College, Chicago, in 1936. He entered the army from the Medical Reserve Corps in June 1942. Dr. Larimore is also the recipient of the Legion of Merit for his work in the Office of the Surgeon General.

Captain Peter Volpe

Capt. Peter Volpe, Columbus, Ohio, was recently awarded the Bronze Star for meritorious service as medical corps executive officer with the 76th Armored Medical Battalion. He received the award for action in France, Luxembourg and Belgium from December 1944 to February 1945, when, "by his courage, technical skill and outstanding devotion to duty he aided materially in the rapid evacuation of casualties and the saving of the lives of many American soldiers." Dr. Volpe graduated from the Ohio State University College of Medicine, Columbus, in 1931 and entered the service Sept. 4, 1942.

CHANGES

Tumolo, Mauro A., Lt. Comdr., Green Cove Springs, Fla. Reported on list 12-1-45. Was not relieved from active duty.

ORGANIZATION SECTION

ANNUAL CONFERENCE OF SECRETARIES AND EDITORS OF CONSTITUENT STATE MEDICAL ASSOCIATIONS

DR. CREIGHTON BARKER, New Haven, Conn., Presiding

FRIDAY, FEBRUARY 8—MORNING

DR. R. L. SENSENICH, Chairman of the Board of Trustees: These meetings have been of tremendous interest and of equally great importance in the conduct of the affairs of the Association. Discussions have from time to time varied from subjects of national importance to matters that were more local. At present we are confronted with a national situation which takes precedence over most of the subjects which we might otherwise discuss. The statement has been made that medicine is maladjusted to the social structure. The implication is that medicine has made no changes and has not progressed and society has by reason of its changes gone entirely away from us. To that I take exception. I think medicine has been realistic and has not been maladjusted or backward. On the contrary, it has brought to the whole people a true reflection of the advances in medical science. I would say society was maladjusted to its own advances, at least economically, whereas medicine has continued to function and has served all. The economic side of medicine offers some problems which are not impossible of solution. If there are changes to be made it is our responsibility to assist in bringing about those changes, but it is important that we know in what respect changes shall be made and, if not extensive, the modifications in our economic pattern should be of a kind which will make medicine available to all the people. Our policies are determined by the House of Delegates, but it is up to the Board of Trustees and the representatives of the constituent societies to shape the pattern of medical care within the structure as set up by the policies that the House of Delegates has put down for us. The responsibility lies to a greater extent with you who represent the constituent societies, as editors and secretaries, probably to a greater extent than any other group in the organized profession. You do much to form the pattern of activity in the various states and to assist in the carrying out of that pattern; in addition you are in better position to reflect the attitude of the public in your contacts in the constituent and component societies than is any other group. Some attitudes are local and some plans are local. Some of them are not practicable of national application, no matter how active the local enthusiasm in promoting them. This, then, is a clinic. We have brought to this clinic those men who can report on conditions and provide new thought with reference to meeting various problems on the basis of the established facts, diagnoses, methods and, what is still more important, the results of those treatments. I want to emphasize the importance of knowing the unsuccessful efforts as well as the successful ones. Dr. Leland used to claim that nobody ever told about the failures. That is unfortunate. Perhaps competitive thinking between state societies has reacted in the direction of making us all want to have many successes checked to our credit. We are disinclined to be realistic or quite frank in the admission of our failures, and especially in calling attention to the things that made the failures.

Current Status of Medical Legislation

MR. J. W. HOLLOWAY JR., Director, Bureau of Legal Medicine and Legislation: Just prior to the Christmas recess congressional action was completed on two measures that are of particular interest to the medical profession. Both related to veterans. Completion was half-way had on another bill, the Hill-Burton hospital construction bill. The Servicemen's Readjustment Act, or the so-called G. I. Bill of Rights, was enacted in 1944 and has been in operation for about eighteen months. During that period a number of questions have arisen concerning the applicability of the provisions of title 2 of the law, which relates to educational benefits to the returning medical officer. These questions were given careful consideration by a subcommittee of the Committee on Postwar Medical Service, and many conferences were held in Washington with the officials of the Veterans Administration in an effort to obtain answers to these questions through administrative rulings.

When amendatory legislation was introduced in the late summer last year, this subcommittee filed with the Senate Committee on Finance a statement recommending four or five changes in the G. I. Bill of Rights in the interest of the returning medical officer. All of these changes have become effective. Three or four of them were incorporated into the law itself, and the other suggestions have been adopted through administrative ruling. Here is what the subcommittee recommended to the Senate Committee on Finance, and the action taken by the Congress on those recommendations:

The subcommittee recommended the removal of the requirement in the case of the medical officer over 25 years of age when he entered service that he prove that his education was interfered with in order to qualify for educational benefits beyond the one year period. This imposed quite a hardship on some of the returning medical officers, and while the attitude expressed in Washington indicated a liberal construction of this requirement, the medical officer was required to file his application with the regional officer of the Veterans Administration having jurisdiction, and there was a possibility of different constructions being made in different regional offices. Now the returning medical officer will be entitled to such educational benefits or a period of educational benefits commensurate with the time he served in the Army or Navy without regard to the age of the medical officer at the time he entered the service.

The subcommittee recommended that the government pay (in the case of a short refresher course) the tuition charged by the institution subject to the $500 limitation and not pro rate the fee as has been considered necessary under the original law. If a returned medical officer pursued such a course for eight weeks at a cost of $250, under the original law the government would not pay the $250 but would pay the proportion of $500 that eight weeks bore to an ordinary school year of thirty-two weeks, or would pay $125 and the medical officer would be required to pay the other $125. Public Law 268, which is the law that amended the G. I. Bill of Rights, provides that in the hypothetical case stated the government would pay the entire $250 and there would be charged against the veteran's period of eligibility the proportion of an ordinary school year which the cost of the short course bears to $500. Since the tuition in this case was $250, and since that is one half of $500, the medical officer will have used up one-half year of his period of eligibility and not merely the eight weeks during which he pursued his course. The subcommittee recommended that the educational benefits be made available to the veteran medical officer while on terminal leave. This was not possible under the original law because of the requirement that the veteran must be discharged or otherwise honorably separated from service before the benefits were available. The new law does provide that the benefits of title 2 and title 3, relating to education and to loans, are available to veterans on terminal leave, with the restriction that subsistence benefit allowances are not payable until the veteran has separated from the service. This amendment was made effective as of June 22, 1944, which was the date the original law was enacted. The fact that Congress did make this particular amendment retroactive constitutes, I think, a justification for an application by a medical officer for reimbursement of funds expended prior to the enactment of this law for refresher courses during a terminal leave period.

The subcommittee made two other recommendations which can be treated together. It recommended that accredited hospitals be specifically recognized in the law as being educational institutions and as such entitled to tuition payments, and that former medical officers pursuing residencies or internships be considered as students and as such be entitled to the subsistence allowances. Prior to recent date there had been much uncertainty as to whether a hospital could be considered as an educational institution under the law and as to whether an intern or a resident could be considered as a student. These recommendations were not included in the new law, but, as indicated in a statement that was published in The Journal on January 26, they have been administratively determined in line with the recommendation of the subcommittee of the Committee on Postwar Medical Service. In brief, a hospital is considered as an educational institution; it may receive tuition payments, and a medical officer serving a residency or an internship in the hospital is considered as a student and is entitled to the subsistence allowance of $65 per month without dependents, or $90 per month if the veteran medical officer has dependents.

Another change in this new law not specifically recommended by the subcommittee permits a veteran to foreshorten his period of eligibility by having paid for him the cost of an educational course in excess of $500 for an ordinary school year. If he does so there will be charged against his period of eligibility the proportion of an ordinary school year which such excess bears to $500. Assume that a returned medical officer, for instance, has a two year period of eligibility. He desires a one year refresher course that will cost him $750. Prior to the recent amendatory law only $500 of the $750 could be paid by the government. Under the amendment the veteran may elect to have the government pay the entire $750, and his period of eligibility for benefits will be reduced not by one year but by one and one-half years.

The amendments that were made to title 3 of the G. I. Bill of Rights relating to loans were for the purpose of simplifying the procedures and extending the benefits. They are too detailed to discuss here. Briefly, 50 per cent of any loan made to a veteran for the purpose set forth in the law, within ten years after the termination of the war, may be automatically guaranteed by the Veterans Administration subject to the limitation that the amounts guaranteed may not exceed $2,000 in the case of a non-real estate loan, or $4,000 in the case of a real estate loan. As heretofore, the loans must be negotiated with a lending agency such as a local bank. No loans are made by the Veterans Administration itself; it only guarantees a part of them. Not more than 4 per cent interest may be charged on any guaranteed loan.

VETERANS ADMINISTRATION

On January 3 the President approved Public Law 293, a bill establishing a Department of Medicine and Surgery in the Veterans Administration. Its provisions were analyzed in detail in The Journal, January 5. Its objective is to provide a better quality of medical care for veterans by offering a greater financial inducement to physicians to associate themselves with the Veterans Administration, by providing for the selection and retention of medical officers without regard to Civil Service requirements, by affording opportunities for medical officers to qualify as specialists with additional compensation and by affording opportunities for postgraduate residencies in veterans' hospitals. The general objectives of this law are admittedly meritorious.

The Hill-Burton hospital bill, which passed the Senate on December 11, is in substantially the same form in which it was reported by the Senate Committee on Education and Labor. It is now pending in the House Committee on Interstate and Foreign Commerce. In the report of the Senate Committee on Education and Labor, Senator Murray filed a reservation to the report of the full committee. He expressed the belief that the bill includes a bad and dangerous administrative arrangement in that it assigns certain essential administrative functions to the Federal Hospital Council; that it devolves too much authority on the states with respect to the use of federal funds. He urged that the federal regulatory power should be extended over the operation and maintenance of hospitals to be constructed under this program.

In reporting this bill to the Senate, the Senate committee suggested certain important changes in the original bill which were thereafter adopted by the Senate. Briefly, these changes were as follows:

The reported bill provides for a five year program and authorizes annual appropriations of 75 million dollars for each of the five years plus unappropriated and unexpended balances. The original bill suggested an appropriation of 100 million dollars for the first year and unlimited appropriation for an unlimited number of years thereafter.

Second, an authorization in the original bill of 5 million dollars for state administrative expenses was eliminated on the theory that the states should be able to handle this aspect of the program without federal aid.

Third, a formula was included for the allotment of federal funds which will tend to eliminate any administrative discretion in making allotments.

Fourth, the term "Public Health Service" was redefined to exclude any reference to medical care.

Fifth, in the original bill it was required that a state plan embody a construction program which would be in accordance with standards to be prescribed by the Surgeon General with the approval of the Federal Council. In the reported bill general requirements are specifically set out, and the federal government's regulatory control is limited to such general requirements. These requirements are laid, in the main, to the number and general manner of distribution of hospitals to be constructed under the program.

Sixth, a designation of the council on the federal level was changed from the Federal Advisory Council to the Federal Hospital Council, because in the opinion of the committee the functions of the council were not solely advisory.

Seventh, there was included in the bill, as recommended by representatives of the Association who participated in the Senate hearings, a provision denying to any federal officer or employee the right to exercise any supervision or control over the administration, personnel, maintenance or operation of any hospital with respect to which any federal funds are made available under this program.

When the bill was on the floor of the Senate, Senator Wagner and Senator Murray offered some six or seven amendments to cure what they thought were the bad features of the bill. One of these amendments would have denied to the Federal Hospital Council any functions whatever other than purely advisory. Another would have conferred on the Surgeon General jurisdiction over the maintenance and operation of the hospitals to be constructed. Still another would have assured that such hospitals could be utilized by all practitioners in the community in which they were located who were licensed to practice, and so on.

The principal support of these amendments came from Senator Murray and Senator Wagner, and all the amendments offered were rejected with the exception of one, and this amendment relates solely to the distribution of public health centers. In the bill as reported to the Senate, the provision was contained in it that the distribution of such centers shall not exceed one per 30,000 of population. Senator Murray suggested an amendment to this provision, as follows: ". . . except that in states having less than twelve persons per square mile, the distribution shall not exceed one per 20,000 population."

The lack of support that Senator Wagner and Senator Murray were able to get in this instance may possibly reflect the idea that the Senate as a whole does not find itself in agreement with the philosophies of these two senators. The bill now is before the House Committee on Interstate and Foreign Commerce, and hearings on it were scheduled for February 25.

DISCUSSION

Dr. Joseph S. Lawrence, Director, Washington Office, Council on Medical Service and Public Relations: A Senate joint resolution has been introduced by Senator Wayne Morse of Oregon. It provides that the Children's Bureau shall be given authority and money to do three things: First, make studies of the health and physical status of children of school ages; second, make studies of the facilities and services offered by schools for the correction of physical defects of school children of school ages; third, recommend the use of and demonstrate in representative urban and rural areas methods of conducting school health examinations and provide school health services. I spoke with Senator Morris about the origin of the bill, and he said that the Children's Bureau of course knew about it, but he was particularly interested because a woman's league had given it to him. Women's organizations are the lively organizations at the present time in studying and advocating changes in our health program. I was invited to be present yesterday afternoon at a discussion before the League of Women Voters of Washington, D. C. They invited a doctor from the Department of Agriculture to represent one side of the question and me the other side. It was a round table discussion. I don't believe any convictions were made at the time, but I do think many of the women got a different idea of the health program generally, at least from their questions as the afternoon progressed, and when the meeting was over some of them came to me and indicated that they had obtained a different idea of the whole situation. However, I believe that many of them were wives of government employees, and after all they would vote today for a government system of medicine. Senator Pepper, on his return from a tour around the world, or rather a tour to the Far East and the war areas, stopped for quite a while in England and talked with Beveridge. He is persuaded, I am told, that we should have some kind of system that follows the lines set out by Beveridge; that is, we ought not any longer have our welfare and social security and various items scattered, but they should be united in one system, one government administrative group. He believes that the Beveridge scope is not too large. I am told, however, that he does not endorse the Beveridge plan 100 per cent; he feels that we can work out something different for ourselves.

DR. HENRY A. DAVIDSON, Trenton, N. J.: Mr. Holloway, with reference to the acceptability of osteopaths in the medical department of the Veterans Administration, do you know whether General Bradley in fact intends not to appoint osteopaths or whether indeed he has any choice in the matter? Is he going to let the clause remain in the bill and not appoint osteopaths?

MR. HOLLOWAY: It is my understanding that it is permissive and not mandatory.

DR. DAVIDSON: There is no provision, as it is now set up, for the osteopathic organizations to insist that they have an absolute right in such appointments?

MR. HOLLOWAY: Not under this law.

DR. CARL B. DRAKE, St. Paul: I should like to ask for a little information with regard to the public health centers. I am from a city and do not know what the views of country practitioners are, particularly, but I have an idea that many of them need (in the way of hospitals in sparsely scattered districts) places where they can take emergency operations, for instance, and fractures and obstetric cases. I understand this bill is going to be limited to public health centers. Can any one tell me just what a public health center will include in its activities?

MR. HOLLOWAY: They exclude medical care.

DR. SENSENICH: There was much discussion of the bill in the Senate, and there was much objection to giving blanket authority for all kinds of treatment centers, the idea being that a treatment center, with an x-ray and small laboratory equipment, would tend in many instances to stimulate or rather encourage doctors to do things for which they probably were not competent. In connection with the Hospital Association, no objection was made to those centers provided they were extension departments or an extended outpatient department, rather, of some existing medical center, where obviously there would be a trained roentgenologist and trained laboratory worker. Finally the discussion swung about to where it was thought better to exclude it entirely with the idea that, if the program went through with sufficient money to create facilities in the way of hospitals, probably it would not be too difficult to arrange so that those services were possible in the hospitals, and they would not be too far away to deal with and to provide facilities for the proper care of patients who needed special service; it would be better to confine those units to educational and public health work.

MR. HOLLOWAY: Dr. Sensenich, wasn't it also suggested by the Senate Committee on Education and Labor, in its report, that the functions of these health centers would be determined on a state level by the state law?

DR. SENSENICH: That is right.

MR. HOLLOWAY: And would not be provided in the federal law. So, what the activity can be, carried on in a public health center, would be determined by the law in the state in which it operates.

Plans for Medical Care in Rural Areas

DR. F. S. CROCKETT, Chairman of the Committee on Rural Medical Service of the American Medical Association: The Committee on Rural Medical Service is one of the more recent efforts of the Board of Trustees to do something of a constructive nature, if possible, for the help of people in rural areas. The one million members of the American Farm Bureau through its auxiliary, the Associated Women of the American Farm Bureau Federation, has been interested in rural medical service for a number of years. Several years ago they appointed a Committee on Rural Health to study the problem of medical care created by the reluctance of young physicians to locate in smaller towns and villages. This, together with the advancing age of the doctors remaining, has created deep concern among the farmers. The American Medical Association was invited by them to assist in the study and solution of the problem. The Board of Trustees appointed a Committee on Rural Medical Service. We had our first meeting last July. We learned that the bureau was opposed to compulsory legislation such as the Wagner-Murray-Dingell bill; however, they recognized that a need existed in many rural areas and feared that there would be federal legislation if something could not be done by themselves as consumers, with the help of the medical profession. Since this is really a community problem multiplied several hundred times, it was apparent that it could not be solved on a national level by either the Farm Bureau or the American Medical Association. We found that the Farm Bureau was organized very much as we in the American Medical Association are organized: If anything was to be done it must be done by the state and county bureaus, as we must act through our state and county societies. It was decided to ask the state societies of medicine to form rural health committees to meet with like committees of the state Farm Bureaus, these committees to confer and organize the counties as and when needed. On our part, a letter was sent to the secretary of each state reporting the conference and the plan. To date some nineteen states have appointed committees or designated some existing committee, and seven states have announced their intention to comply. This project is a full time job for any committee alive to the possibilities inherent in this plan.

Much of the agitation in Congress about the paucity of medical attention arises from the absence of doctors in rural areas. This is not a local condition, in that it exists in practically all the states of the Union. Hence the broad appeal to nearly all legislators who have a rural constituency. If we can show to these congressmen and these senators that an earnest effort is being made to help these communities, much of the immediate heat will be cooled. We all know that doctors cannot be assigned to these places. We also recognize that an opportunity to earn a reasonable living amid satisfactory social surroundings are two of the important factors. Granting that these conditions are met, what can be done to attract well qualified physicians, especially recent graduates, to practice in these communities, often at some distance from a well equipped hospital?

The Hill-Burton bill is generally expected to pass. This bill is expected to provide certain kinds of facilities, especially helpful in rural areas, and it is with that idea in mind that the Farm Bureau has been supporting it. It is at this point that state and county committees, together with their Farm Bureau counterparts, can be of great value in making the Hill-Burton bill solve a really local need rather than a political objective. The unit of population to be served, the unit of mileage to be covered and the type of facility best suited to each community when viewed individually in relation to its professional personnel and when seen as a part of a larger group about a well equipped hospital—all these must be determined and tailored to meet the needs of each locality and larger area, and who can better do that than the local medical profession and the state medical profession together with the farm bureaus of comparable areas?

The term "diagnostic or health center" has not been defined. It is an elastic term. It may mean housing for doctors and dentists, public health officers, laboratory and x-ray equipment. Down in Georgia they assume in their survey that this is to be the definition of a health center. They also suggested that in certain instances adding emergency beds for accident and obstetric cases might be desirable, on the basis of 1 or 1½ beds per thousand of population. All of these might be very helpful to the well trained physician, and its presence in the community would promise much needed diagnostic aid to those adequately trained. If facilities are to be placed here and there through the operation of the Hill-Burton bill, some provision must be devised to maintain a high standard of usage, and I think that is another point in which we must all be very much concerned.

Our recognized hospitals submit to inspection and regulation by the American Medical Association through its Council on Medical Education and Hospitals, resulting in a higher standard of medical care. The benefits of this practice might be extended to the diagnostic centers at a distance if they could be made an outpatient responsibility of the hospital center of the area.

The chairman of this committee made two trips to Washington, one last September, to confer with representatives of the Dairy Cooperatives, representing some 350,000 milk producers in some forty-two states. Following this conference their board of directors adopted a policy opposed to compulsory types of legislation.

If we are to secure for our rural areas the fullest benefit from the Hill-Burton bill, we must have active committees in every state having rural areas with health problems. Now, before the bill becomes law, liaison must be established with interested farm groups, probably from the Farm Bureau. Agreement should be sought covering procedure, contact with the government or the responsible state agency in support of sound administration, preliminary surveys, and the whole thing blueprinted to your satisfaction. In March 1944, just a year ago, the Farm Foundation sponsored a meeting of the Farm Bureau, the Grange and the Farmers Union, assisted by many representatives of the United States Public Health Service, the Department of Agriculture, several colleges of agriculture and other interested individuals. A comprehensive survey of health needs all over the rural part of America was made. Last September this committee met at the Farm Foundation again with representatives of the Farm Bureau, the Grange and the Farmers Union. It seems that they have a national committee composed of representatives of these farm groups, who consider rural health problems, and it was with that group that your committee met to discuss the fourteen point program as it affected farmers. All this is related to you to show you the interest that the farmers themselves have in their own farm health programs.

In July 1945 was held the first conference for county leaders on medical care, health service and facilities in Ohio. This was an interesting conference. It was held at the Ohio State University, but the value of conferences of this kind results from the fact that there has been a good deal of preliminary groundwork done through the extension department, and in this case the Farm Foundation had helped to finance some one to make a special survey of the farm situation in the three general sections of Ohio.

The value of conferences such as this lies in the meeting of farmers with leading public health workers, dentists and leaders of the extension services of the agricultural colleges, resulting in a better understanding of the many economic, housing and social conditions that must be solved in attracting the right kind of doctors to where they are most needed and under conditions where they can do the most good. State committees within your state medical societies on rural medical service could initiate like conferences in other land grant colleges, and I am anxious that that be studied as to one of the things which could be done this year on a wide basis. Some states have already done much in surveying their health needs.

Last summer the state of Georgia published a most interesting survey of rural and urban health needs and facilities. The public health program was prepared by the Health Panel of the Agricultural Industrial Development Board of Georgia. It covered the period 1940 to 1944. The economic condition, the social factors involved and existing facilities were surveyed both in rural and in urban communities. The entire state was covered, and based on that most comprehensive study they made some definite recommendations.

I have just received this copy from Virginia. They have just published a report of their Advisory Legislative Council on medical facilities available in rural areas of the state. They have followed through with the same general idea which I hope all our states are doing and which the rural medical service committees of our states could be helpful in initiating, if they will. Shortage of professional personnel was found greatest in rural areas. Six counties had no active physicians at all in Virginia, and fourteen counties had only one physician to 6,000 or more of population. The remedy suggested including placing facilities for diagnostic and health purposes at strategic points for the use of physicians and public health services; also a large loan fund for rural youth in obtaining a medical education granted on a pledge to practice for a time in rural communities was made. The latter point has been tried a number of times with more or less success, many times without accomplishing much good, but it still has its possibilities, and in Virginia they are going to give it another try.

We should like to have a round table conference some time, probably the first week in April, at which chairmen or members of these rural committees from the states would come in and we could get members of the Farm Bureau committees to attend and see what can be done in such a conference to make effective this sort of effort. It is easy for committees on national levels to meet, to draw resolutions, to affirm general principles, to go home and meet in another year. If this committee is to be of any service to you, to the profession and to rural America, we must have active committees in the states; we must give them jobs and work to do, which we are planning to get busy on now; and from that we must get down to the county level where the actual information many times must be obtained to complete the job.

DISCUSSION

Dr. Victor Johnson, Secretary, Council on Medical Education and Hospitals: These farm groups are vitally interested in collaborating with the medical profession, in meeting the problems of rural medical care. This job cannot be done on a national level. This educational process has to be carried to the grass roots, to the farmer himself, and that must be done through local organizations, through your own committees collaborating with the local committees in the states. The necessity for this can be exemplified by an experience in Virginia, where the Hospital Service Plan conducted a number of surveys, one of them in Craig County, which was selected as an ideal county to enroll farmers and other rural inhabitants into the Hospital Insurance Plan. It was found that 95 per cent of the families did their banking in two banks in one of the cities of the county. It was decided to conduct this campaign through the banks. The banks were to deduct the premiums from the bank accounts of the farmers. They expected that of the 950 families in this ideal county perhaps 500 would enroll. There was a rather high pressure campaign, using that term in the better sense of the word, a well organized campaign to enroll these families. They got not 500 families but 75 families. They set about analyzing why this failure occurred. They decided there were three major factors in that community: In the first place the farmers are not used to having things deducted either from their incomes or from their bank accounts, as is true in the case of urban population Second, farmers take a little longer to make up their minds. They want to think things over a little longer than some of the other people with whom we are used to dealing. Third, they are not as used to the employment of hospitals in times of illness as is true of urban populations. All of these points are matters of education of the individual farmer, which must be carried out on the basis of local educational organizations.

Dr. Crockett mentioned that the Farm Bureau has a membership of one million. Actually the individual membership is something like four times that, because the membership of one million represents family memberships, and on the average in these memberships there are about four individuals per family. Therefore we are dealing with a potent and vocal and powerful cross section of the farm population.

CHAIRMAN BARKER: I realize that many of you come from more rural or agricultural states than I do, but I think farmers are the same almost everywhere. I imagine the farmer adjusts himself to his environment and gets along pretty well. I am not a bit surprised about the seventy-five families taking the hospital plan. They are pretty independent fellows.

DR. SENSENICH: Has any thought been given to the idea of central hospitals at selected spots and the giving of some sort of transportation or ambulance service, or otherwise, with the idea of concentrating the ill some place where they can be given good service? I am wondering if it is practical, or whether any thought has been given to utilizing the Hill-Burton bill or some other means of financing locally, if possible, the establishment of facilities at proper points and then providing some kind of transportation for people who are ill

DR. ARTHUR J. OFFERMAN, Omaha: I am a member of the Nebraska Blue Cross and president of the Nebraska Surgical Plan. We think we are getting some of the rural problems in Nebraska. In western Nebraska, in the small town of Morrow, with about 800 population, we estimated that there were about 200 families. We started a campaign to enroll this small country town in our hospital plan. The campaign was carried on through community effort. In about two weeks we were successful in enrolling about 160 of the 200 families. We thought we were quite successful in doing that. Probably in eight or twelve months we will go back and try to enroll them in our prepayment plan for maternity and surgical care. In the fifteen months we have been in operation we have been successful in enrolling twenty truly rural groups. These rural groups consist of school districts and extension clubs and project clubs. We think the average enrolment in these rural groups amounts to about forty people in each group. Our field director has been active in this, and we think it is due to his single efforts that we have been able to get to the rural groups at all. We have a lot of wide open spaces in western Nebraska, and I have talked with many men in the general practice of medicine, men who are practicing medicine and surgery and obstetrics. I have asked them "What is your experience? How are you doing it? What about maternity care?" More and more of those men are working about hospitals. Even though they are situated 20 or 30 miles from a hospital they are doing most of their maternity work in the hospital. I asked them how they do it. They said "Our roads for the most part are pretty good. They are all surfaced, year round highways, and 35 miles means thirty-five or forty minutes at the most." Many of us live in the city and drive for twenty minutes to make a friendly visit, so twenty minutes farther isn't any great extension of effort. There is an increase in the use of hospitals for all types of care. In my own city of Omaha there were about 5,000 babies born last year, and 4,500 of them were born in hospitals. I think in the rural areas, in the smaller cities and smaller towns, there is great utilization of hospitals. The hospital situation is difficult; there are not enough beds; there is the constant difficulty of getting a patient admitted.

DR. D. G. EDMUNDS, Salt Lake City: Speaking for Utah, may I say that the population more or less follows the main lines of either railroad or automobile transportation. Probably the southeastern part of the state would suffer most. It is sparsely settled, and maybe 75 miles at the most would have to be driven over fairly good roads to reach a hospital; otherwise the country hospitals have been sponsored either by the community or by individuals and are fairly well set up. The state medical association has been studying this question, but we have not taken a particularly active part up to this time, although we intend to. In Utah the Mormon Church is predominant, and the presiding bishops have indicated that they are going to set up rural hospitals on the basis that if the community will put up 50 per cent the church will supply the other 50 per cent. That would make hospitals (the sites of all of which have been selected) available to practically all the rural places in Utah. In any state of that type there are farmers, ranchers and so on who have no telephones or who drive over roads that are pretty bad; but they would be in the minority. On the whole we are pretty well supplied, or will be, with the plans now under way. Regardless of whether the Hill-Burton bill passes or not, we are opposed to federal aid. We feel that it is not necessary and that we can get along very well without much of it.

DR. SENSENICH: Doctor, does it bring the costs down when they do not have great mileage to pay, or is that a factor? The complaint is made that the people who live distances away have to pay so much to have a physician come to see them. I wonder, if they were transported to a hospital, whether it would make very much difference.

DR. EDMUNDS: It would. If a doctor makes a 70 mile trip and charges his mileage plus his fee, naturally it does cost something in an individual case. When it comes to transporting and when the roads are good for driving, there is no reason in the world why almost any one cannot reach a hospital within a comparatively short time. I think it would be from twenty to forty-five minutes at the most, except in the southeastern corner of the state.

DR. SENSENICH: Is there any ambulance service as a community service or organization service?

DR. EDMUNDS: Not unless it is some little local place that has organized an ambulance of its own; but that is not general yet. I do not feel that this rural fear of medical care is going to be great, at least not in our state. We cannot have a medical society in every county; sometimes there will be five counties that will make up one medical unit. Of course there are some sparsely settled areas that may suffer.

DR. SENSENICH: What is the attitude of your local authorities in connection with the indigent under those circumstances? Do they have difficulty being admitted to hospitals for care? Is that an argument to be used against it?

DR. EDMUNDS: If this feeling against federal aid is sponsored as it is going to be, and the hospitals have already planned on it through the Mormon Church in the communities, they are going to have more trouble entering and seeking care, whether they are Mormons or not.

MR. JOHN HUNTON, San Francisco: California is far enough west to qualify under your request, Dr. Sensenich. We have had this problem of trying to cover the rural residents with a prepayment plan. We decided finally that the best method was to work through one or another of the farm organizations. We have three large groups, the Associated Farmers, which is comparable to the Farmers Union in some other cities, we have the Farm Bureau Federation, and we have the State Grange. The State Grange in many places constitutes more or less a social gathering, but it happens to be a rather active organization in California, with about 30,000 farm families as members. Right now we are working with the State Grange to sign a contract with the California Physicians' Service for complete care, under a regular California Physicians' Service contract, for all those 30,000 families, with the State Grange acting as the selling and collecting agency, the California Physicians' Service putting out the promotional material and working with the State Grange and enrolling the groups in their various centers. That thing has not yet been developed fully, and the State Grange has asked for several concessions which are not quite along our line of thinking; but we are working amicably with them and we hope that within another sixty days we shall have a contract signed with that group to take care of 30,000 families. From that beginning we hope to be able to make a break into the Farm Bureau Federation, into the Associated Farmers and into the various cooperatives, which, as you know, not only form a rather tight group in themselves but which also are handling the money of their members and are in an ideal position to make the collections under any prepayment plan.

DR. EDMUNDS: I should have added that the Blue Cross came in there a year ago and already has signed up 27,000 members. It is going well through that locality. The state of Utah will soon have a surgical plan, and it is expected that the Blue Cross will sell it in connection with its hospital service.

Mr. C. S. Nelson, Columbus, Ohio: We find too frequently that some farm people want cheap medical care instead of health, and they have to be told that they cannot have health with cheap medical care. It is a question of improving the economic conditions, the health departments, better facilities, better living conditions and so on; and they also realize that they have the problem on their hands of keeping their own children on the farm. The population figures will show that. It is difficult to get a young physician whose wife and he were born in a city to move into a rural area, largely because of certain social and economic conditions. If we can point out their responsibilities to them and then try to do the things we can do, we shall arrive at a common ground. That is exactly what we have done in Ohio. I think the greatest difference in Ohio at the present time is largely on the question of the cost of the financing. It is a substantial group in Ohio who believe in consumer cooperatives. We do not. If we can work out some plan to finance and distribute medical care, the other problems will be met. They realize that they have a definite responsibility too along with us.

Mr. H. T. Sethman, Denver: In Colorado we have three counties or areas which we refer to as Parks—North, Middle and South. These parks are so located that they have a mountain range, you might say, between them. The population of one of those areas is perhaps 2,000, another around 3,000 and the third about 1,500. At present we have three physicians in the one county. The area extends probably 70 miles in length. The areas are broken up with mountain ranges running between them. The population follows a stream, and the branches are established along that stream. They extend probably for 40 miles up in my direction. The roads in these areas, except for a main highway that extends through the areas, are poor. They are passable in the summer, but most of them are snowed up in the winter. In the past few years we have had some progress made in getting service plows to clear some of the roads so the people could get to the highway or into a nearby city or to their nearby ranches, but that is only on the rare occasion when some one is sick. Then you take a week off to get the county commissioners to decide to plow the fellow out so the doctor can get to him. The question of how adequate the physicians' supply is resolves itself like this: Say a physician has a call to Breckinridge, 70 miles away. He can't make many such calls in twenty-four hours. Many people, of course, get sick at night. When a storm is raging, the physician drives as far as he can in his automobile, then he gets into a feed sled which takes him 6 miles farther, and then another sled takes him the rest of the way. What are you going to do about it? Are you going to have sufficient physicians for every family, or are you going to solve it more by having the economic situation remedied so that these people can get into the towns? It isn't a matter of distance. We have provided hospitalization for these people in good hospitals, not in our own community. The hospital proposition is not so difficult if you can get to the ill in an automobile, provided they are sick enough to go to a hospital; then you can get them there. Many of the obstetric cases are done in the homes in those areas, but the folks have been educated to the fact that it is preferable for them to go to a hospital. Hospital facilities are being taxed in our state generally, and in our hospital centers space is not too available at all times. Of course, the women make arrangements somehow or other either to get to the hospital or to be taken care of at home. As far as rural ambulance service is concerned, that is not such a big problem. Few of the people do not own automobiles, and by making certain arrangements in any auto, other than a coupé, you can easily and comfortably transport a patient to the hospital. The county commissioners like to overlook these facts because it would mean a little more expense to build roads into these areas so that the people could get in and out. I don't know how that problem is going to be solved. If there was a hospital center in an area and you had the personnel to make it a good, serviceable center, how would that hospital operate under the conditions we have to face now? The patients can't get to it. Frequently the passes are closed between the areas because of snow. The pass was closed just before I left, except at the one main pass, and snowslides many times keep one from getting through in a car; however, we do have to tunnel into Denver to get through, sometimes. Even if adequate hospital service was supplied, if the people living in that community were taxed or requested to pay so much to support it, I don't believe they would want it. People from one area cannot get into the other.

As far as getting physicians into those communities is concerned, I think the largest town in any one of these areas has a population of around 400 people. There are just so many physicians who can make a living in that area. It is my opinion that any of the young physicians who would choose a place like that, where they could barely make a living, probably would not represent the quality of men they should be for the kind of care we are talking about.

Dr. A. J. Bowles, Seattle: In the state of Washington in the last legislature a bill was passed to raise money to establish hospitals in communities sparsely settled, which helped to settle the hospital problem to a certain extent. We have a man in Washington by the name of Shadid who, I believe, came from Oklahoma. He is establishing hospitals, selling the farmers at the rate of $100 a share, and sponsoring the hospital he plans to build. He is going to hire a big staff of doctors to staff the hospital. As a state bureau we are attempting and at the present time are taking small groups of a Grange, 1,500 in certain areas, and are giving them full coverage for hospital care, medical care, and so on, not taking the whole state at once, so we can get some idea of what it is going to cost us. I believe that we shall get to help these farmers.

(To be continued)

Medical Legislation

MEDICAL BILLS IN CONGRESS

Disease Prevention

Senator Pepper, Florida, has introduced S. 1875, to authorize the President to mobilize at some convenient place in the United States an adequate number of the world's outstanding experts in an effort to discover means of curing and preventing cancer. An appropriation of $100,000,000 will be authorized to enable the President to carry out the provisions of the bill. A companion bill introduced by Representative Neely, West Virginia, H. R. 4502, is pending in the House.

Senator Langer, North Dakota, has introduced three bills relating to the prevention of disease, S. 1883, S. 1888 and S. 1891. These bills, respectively, propose each an appropriation of $3,750,000,000 (1) for use by the Public Health Service to promote programs for the prevention, diagnosis and treatment of cancer, (2) for disbursement to Sister Elizabeth Kenny for use in establishing and maintaining facilities for the hospitalization and treatment of persons suffering from infantile paralysis, and for investigation and research with respect to the origin, causes and means of control of the disease, and (3) for use by the Surgeon General of the Public Health Service to provide the means for securing a specimen of the urine of each person in the United States and the examination and analysis of such specimen, a report to be made to the health authorities of the municipality or the county wherein the person resides if the examination and analysis disclose the existence of some disease.

Physically Handicapped Persons

Senator Radcliffe, Maryland, has introduced S. 1865, directing the Secretary of Commerce, through the Bureau of the Census, (1) to make a survey of the population of the United States to determine, as far as possible, the number, age and location of physically handicapped persons; (2) to prepare and submit to the President and to Congress a preliminary statement outlining plans for conducting the survey and for classifying citizens found to be physically disabled; and (3) to report to Congress within twelve months the results of the survey. A physically handicapped person is defined as any citizen who, because of (1) congenital deformity, (2) injury or (3) disease, is substantially handicapped in obtaining employment or in self employment

Hospital Construction

Representative Priest, Tennessee, has introduced H R 5628, a bill to amend the Public Health Service Act, to authorize grants to the states for surveying their hospitals and public health centers and for planning construction of additional facilities, and to authorize grants to assist in such construction

Miscellaneous

H R 5645, introduced by Representative Flannagan, Virginia, proposes to enact a Federal Insecticide, Fungicide and Rodenticide Act This bill would regulate the marketing of economic poisons defined to include any substance or mixture of substances intended for preventing, destroying, repelling or mitigating any insects, rodents, fungi, weeds and other forms of plant or animal life or viruses, except viruses on or in living man or other animals

The bill proposing to establish an optometry corps in the medical department of the United States Army, H R 3755, has been reported with amendments, by the Senate Committee on Military Affairs It passed the House Sept 18, 1945

Congressional action has been completed on H R 2348 to bring within the purview of the federal narcotic laws any drug, as defined in the Federal Food, Drug and Cosmetic Act, found by the Secretary of the Treasury to have an addiction forming or addiction sustaining liability similar to morphine or cocaine and proclaimed by the President to have been so found by the Secretary

Hearings on S 1160, a bill to establish a National Neuropsychiatric Institute, have been scheduled for March 6, 7 and 8 before the Subcommittee on Health and Education of the Senate Committee on Education and Labor

STATE LEGISLATION

California

Bill Enacted—S C R 16 X has become resolution chapter No 46 of the Laws of 1945 It is a resolution requesting the state director of finance to appropriate $44 000 for the purpose of carrying out a 1945 law providing for the better protection of the public health by state licensing inspecting, regulating and supervising of public and private hospitals

MASSACHUSETTS

Bills Introduced—H 1209 proposes the establishment of a cash sickness compensation fund to be administered by the Massachusetts division of unemployment security H 1217, to amend the law relating to the taxation of educational institutions, proposes to eliminate the property of such institutions from the exemption provisions if the institution discriminates against applicants for admission thereto because of their race, color, religious creed, national origin or ancestry H 1365 proposes the establishment of a Veterans' Medical Relief Fund to be used for the payment of "all medical bills at any time contracted by any veteran of World War II who shall have been discharged from any of the armed forces of the United States under conditions other than dishonorable, whether such bills are for services rendered to said veteran or to such members of his family as he is under any legal obligation to care for and support" up to a sum not stated in the bill H 1397 proposes to require persons working in restaurants bakeries, stores, bars, etc to submit to and undergo a physical examination as to whether or not said person has tuberculosis or any other communicable disease which might endanger any person he or she may come in contact with the examination to be made at least twice a year H 1398 proposes the establishment of an eye bank in the Massachusetts General Hospital for sight restoration, to collect and preserve healthy corneal tissue from human eyes for transplanting to blind persons who have lost their sight because of corneal defects

Michigan

Bills Enacted—H 13 X was approved February 18 It authorizes the approval of a postwar emergency hospital program for the construction and equipment of a number of hospitals for mentally affected persons S 18 X has become chapter 27 of the Laws of 1946 It provides that persons released from the armed forces who had, prior to their induction, been undergoing training for a trade, occupation or profession shall be entitled to license or qualification under the provisions of the laws covering their qualifications or licensing in force at the time of their entrance into the armed forces Periods of training and practical experience in the armed forces may be accepted by any board of examiners in lieu of the required period

Mississippi

Bills Introduced—H 430 proposes the creation of a Mississippi commission on hospital care to set up and administer a statewide plan for the construction, equipping and maintenance of hospitals, nurses' homes, health centers, clinics and related facilities and in conjunction therewith to prepare a statewide hospital plan and to conduct all necessary studies and surveys incident to developing such a statewide hospital plan S 221 proposes to require all teachers in the elementary and high schools of the state and all other state employees who work directly with children to submit annually to an examination for tuberculosis, including an x ray analysis, by a competent physician or by the state health department

Missouri

Bills Introduced—S 424 proposes to transfer to the State Board of Medical Examiners certain powers and duties heretofore vested in the State Board of Health S 431 proposes to transfer to the State Board of Cosmetology certain powers and duties heretofore vested in the State Board of Health S 432 proposes the creation of a State Board of Chiropody and the assumption by such board of powers and duties heretofore vested in the State Board of Health S 433 proposes to transfer to the State Board of Chiropody certain powers relating to licensing and registration of practitioners heretofore vested in the State Board of Health S 434, relating to the licensing of midwives, proposes to transfer to the division of registration and examination of the state department of education certain powers heretofore vested in the State Department of Health S 435, relating to the licensing of chiropractors, proposes to transfer to the executive secretary of the division of registration and examination of the state department of education certain powers heretofore vested in the State Board of Chiropractic

New Jersey

Bills Introduced—A 133 proposes to prohibit all state boards, commissions and agencies and the board of education from discriminating in any way between ocular practitioners A 147 proposes that the holder of a license to practice a profession, the license or registration certificate of which was forfeited or lapsed because of the passage of time while the holder thereof was in the armed forces, shall be entitled without examination or reexamination, within six months after his discharge, to a renewal or reinstatement of such license on payment of the lawful fee A 164, to amend the medical practice act proposes an addition to the Board of Medical Examiners of a chiropodist to have equal rights and privileges in all matters affecting chiropody A 208 proposes the enactment of a completely new workmen's compensation law and repeal of the existing law A 219, to amend the law relating to the practice of optometry, proposes to make it unlawful for an optometrist licensed under the provisions of this law to engage in the practice of optometry with any corporation organization, group or lay individual A 246, to amend the law relating to the practice of pharmacy, proposes to limit the terms pharmacy' and "drug store' to a business conducted in its entirety as a pharmacy or drug store properly identified as such by signs on the outside of the premises in which the majority of the gross business carried on consists of professional services which may include the sale at retail of drugs, medicines, poisons, chemicals, medicinal vitamins and medicinal vitamin products hormones serums antitoxins, biologicals, pharmaceuticals insecticides disinfectants, sickroom and hospital supplies and surgical appliances A 383, relating to workmen's compensation proposes that whenever a physician surgeon or hospital shall render or furnish medical or hospital service to an employee it shall be the duty of the employer and the insurance carrier if any, to obtain from the physician surgeon or hospital a detailed report in writing of the medical history of the employee and of the examination and treatment of the employee, including the findings, diagnosis, estimates, prognoses and treatments advised and given.

New York

Bills Introduced.—A. 1563 and S. 1469 propose to require the inoculation of all dogs against rabies. A. 1595 and S. 1411 propose the creation of a medical director in the county of Erie who shall be a duly qualified practitioner of medicine and surgery, be a graduate of a medical school and have had at least five years' actual experience in the practice of his profession. He would take over the duties now vested in the medical examiner. A. 1647 and S. 1380, to amend the law relating to divorce, propose to authorize reports of physicians to be received in evidence without the personal appearance of the physicians themselves, where insanity is in issue. A. 1690 and S. 1492, to amend the public health law, propose that no newborn child shall be released from a hospital until a chest x-ray examination particularly of the thymus gland of such child has been taken. The results of such examination must be communicated to the parents of the child. A. 1692 is the same as S. 1354, previously reported. To amend the law relating to nonprofit medical and hospital service corporations, it proposes to authorize the creation of dental expense indemnity service plans. Dental expense indemnity would consist in reimbursement for dental care provided through duly licensed dentists and in furnishing necessary appliances, drugs, medicines and supplies, prosthetic appliances, orthodontic appliances, precious metal and ceramic restorations. A. 1777, to amend the education law, proposes that applicants meeting the preliminary and professional educational requirements of the medical practice act, who present evidence that they have earned a medical student qualifying certificate in accordance with the rules of the department and have served at least one year as a member of a medical corps, detachment or other medical unit of the armed forces of the United States during World War II and were honorably discharged from such service, shall receive and be entitled to receive a license to practice medicine without examination. A. 1811, to amend the hospital lien law, proposes to limit the amount of the lien of a hospital to 15 per cent of the amount recovered by the patient. This limitation, however, would not prohibit the hospital from maintaining legal proceedings to recover the excess. A. 1854, to amend the education law, proposes to prohibit persons licensed to practice optometry from fitting contact lenses into the human eye except under the supervision of a duly licensed physician. A. 2061, to amend the law relating to the labeling of products containing poisonous substances, proposes to prohibit the sale of the following articles unless the container is labeled showing the percentage of the enumerated substances contained therein: aniline antimony, benzene, benzol, cyanogen, ethylene, hydrochloric acid, hallowax, hydrofluoric acid, lead, mercury, nitric acid, phenol, pitch and tar, tetrachlorethane, trichlorethylene, toluol and xyluol. S. 1319 is the same as A. 1167, previously reported. To amend the law relating to hypnotic and somnifacient drugs, it would prohibit prescriptions therefor from being refilled if the prescription bears a direction to that effect. The proposal would further authorize the prescribers to indicate the number of times a prescription may be refilled. If the prescription is silent as to the refilling, then the prescription may be refilled by the pharmacist during a period of not more than six months from the original date of the prescription. A pharmacist would be prohibited from furnishing a copy of the prescription to the patient. S. 1453, to amend the social welfare law, proposes to extend for one year the provisions authorizing emergency service by physicians who are public officers or employees. S. 1520, to amend the workmen's compensation law, proposes to authorize such physician or physicians as an employee or carrier may select and pay for to participate in an examination if the employee or carrier so requests. S. 1563 proposes the creation of a board of examiners in ophthalmic dispensing.

Rhode Island

Bill Introduced.—H. 700, to amend the law relating to the sale of drugs and poisons, proposes that prescriptions for barbital or other hypnotic or somnifacient drugs shall not be refilled or compounded without a written prescription by a duly licensed physician, dentist or veterinarian for each and every refilling.

Bill Enacted.—H. 575 was approved Feb. 20, 1946. It creates a special committee to study the several problems arising out of the administration of the cash sickness compensation act and to make recommendations for amendments thereto.

Virginia

Bills Introduced.—H. 211 proposes the enactment of a hospital licensing and inspecting law. "Hospital" is defined to mean any institution, place, building or agency by or in which facilities for any accommodation are maintained, furnished, conducted, operated or offered for the hospitalization of two or more nonrelated mentally or physically sick or injured persons, or for the care of two or more nonrelated persons requiring or receiving medical or nursing attention or service as chronics, convalescents, aged, disabled or crippled including, but not to exclusion of other particular kinds with varying nomenclature or designation, ordinary hospitals, sanatoriums, rest homes, nursing homes, infirmaries and other related institutions, and undertakings, exclusive of maternity hospitals, to the extent that the same are included within the scope of existing laws. H. 257 proposes that any person who has tuberculosis in a communicable form who, after having been instructed in writing by the local board of health, department of health or health officer or superintendent of any sanatorium of the state to take precautions to protect the members of his household and the public from being infected by tuberculosis communicated by such person, wilfully refuses to follow such instructions shall be guilty of a misdemeanor. H. 289 proposes to require persons dealing in the handling and processing of food for human consumption to submit each six months a certificate from a physician duly licensed for that purpose by the State Board of Health, certifying that such person has been examined and found free from any contagious or infectious disease. H. 303 proposes an appropriation to the department of health for the construction of six health centers in such areas of the state as will most benefit thereby. H. 363 proposes the establishment of a sanatorium for the treatment and rehabilitation of alcoholics. H. 376 proposes the creation of a commission on planning for the state hospital and health center system, the commission to make a hospital and health center survey covering the entire state for the purpose of recommending plans for the establishment and operation of a correlated hospital and health center system. H. 378 proposes regulations for the creation of local hospital or health center commissions. S. J. R. 20 proposes the creation of a commission to make a thorough and complete study of problems related to hospital and medical care, including the need of hospitals and health centers in the state, adequate plans for the prepayment of hospital and medical care for all classes of citizens, with due emphasis on the special needs of rural people, and other items related to the health and medical care of the citizens of the state. S. 164, to amend the law relating to the practice of chiropractic and naturopathy, proposes that any practitioner temporarily licensed, as provided by law, shall be issued a license to practice in his respective branch of the healing arts in Virginia, and such license shall continue in force and effect until suspended or revoked for cause. S. 184 proposes an appropriation to the Virginia Health and Medical Care Council for the purpose of promoting, furthering and fostering better health and medical care throughout the state. S. 226 proposes to authorize the Department of Health to aid in the construction of not more than six health centers in various areas in the state. S. 227 proposes to authorize bodies to be exhumed and autopsies held thereon under certain circumstances. S 237 proposes the creation of an examining board for the certification of clinical psychologists.

Bills Passed.—S. 72 passed the house February 19. It proposes to authorize the state board of public welfare to provide reasonable rules and regulations for the construction, maintenance and operation of boarding homes, homes for the aged and other similar homes, the word "home" meaning "any place, establishment or institution operated or maintained for the maintenance or care of two or more aged, infirm, chronically ill or incapacitated persons." The proposal would exempt from its provisions any hospital, nursing homes, maternity home, children's home or other home or institution which is already or may hereafter be subject to regulation by the board. S. 149 passed the senate February 18. It proposes the creation of hospital authorities to engage in hospital construction, maintenance and operation. S. 166 passed the senate February 16 and the house February 22. To amend the law relating to hypnotic drugs, it proposes that the words "dangerous drugs" shall include, in addition to preparations already so included, "hormones, or hormone drug preparations, whether of natural origin, prepared from the so-called glands of internal secretion or endocrine glands, or whether synthetically produced, by whatsoever trade name or designation, or any compound or mixture thereof; except preparations intended for external use containing hormones in combination with other ingredients unfit for internal administration." No person would be able to sell or give away any such drug except on the prescription of a doctor of medicine, doctor of osteopathy, doctor of dental surgery or doctor of veterinary surgery, lawfully practicing his profession, and prescriptions for hormones could, on written authorizations on the face of the prescription by the prescriber, be refilled a definite number of times as indicated.

RESOLUTIONS AGAINST PEPPER E. M. I. C. PLAN

The Commission on Maternal Welfare of the Medical Society of the State of Pennsylvania, the Philadelphia Obstetrical Society and the Pittsburgh Obstetrical and Gynecological Society have unanimously adopted the following resolution relative to the proposed Pepper plan for maternal and child welfare:

That the Commission on Maternal Welfare of the Pennsylvania State Medical Society is unanimously opposed to any legislation which will perpetuate the present E. M. I. C. plan or any legislation which shall set up any similar plan for maternal and child welfare.

This objection is based on the following facts:

1. There exists no emergency now and there is no public need for any such legislation.
2. Any such program will continue to be solely under the control of the Children's Bureau (or similar bureau) of the Department of Labor and will be centralized in Washington, D. C., and not under the direct control of competently trained physicians.
3. The standards of obstetric care have not improved under the E. M. I. C. plan and cannot be improved by such centralization.
4. The E. M. I. C. plan or any similar plan now under consideration (as in the Pepper bill or the Wagner-Murray-Dingell bill) sets up only a minimum standard of maternal care and at the level of the general practitioner.
5. Adequate maternal care requires a maximum standard of care, and this is not obtained or even approached in the requirements of the present E. M. I. C. plan or the proposed legislation of maternal care as embodied in the Wagner-Murray-Dingell bill.
6. The full and thorough training of future obstetricians has been and will continue to be hampered and interfered with by such legislation. This restriction is felt not only in our medical schools but also in our recognized, accepted or approved hospitals.
7. The medical profession has insisted on adequate maternal care for all expectant mothers. Adequate care denotes maximum care during pregnancy, at delivery and for a definite period after delivery. The present E. M. I. C. plan or the proposed legislation has concentrated on a minimum of care for before delivery only, disregarding entirely the very important phases of the problem, viz., during delivery and through the period directly and for six to eight weeks after delivery (other than a six weeks examination). These are phases in which the accidents and mismanagements make their appearance. No present (E. M. I. C.) or proposed legislation recognizes these two important phases of maternal care; hence the whole plan is full of danger. Maternal and child health depends on all these phases, not on one phase alone with total disregard of one or both of the other two.

All the foregoing factors lead definitely to a lowering of adequate or *maximum maternal care standards, which the medical* profession for the past twenty years has been teaching and practicing in an effort at reducing maternal mortality, which has been accomplished by the profession's efforts. The medical profession through its own organizations has striven to give adequate maternal care to all expectant mothers, and the present E. M. I. C. plan or the proposed legislation sets up only a minimum standard of maternal care. All such legislation, in our professional opinion, eventually will lead to an increase rather than a decrease in maternal mortality, principally because the safeguards are removed and the standards of obstetric care are lowered to a degree below that which we definitely know to be maximum and recognize as adequate.

The Commission on Maternal Welfare is headed by the chairman, Dr. James S. Taylor, Altoona, Pa.

Official Notes

CHANGES IN HEADQUARTERS STAFF

Dr. James R. Wilson, associate professor of pediatrics, Syracuse University School of Medicine, Syracuse, N. Y., has been appointed Secretary of the Council on Foods and Nutrition of the American Medical Association. He succeeds Dr. George Anderson, who resigned to specialize in pediatrics in Rochester, N. Y. Dr. Wilson graduated at Syracuse in 1921.

Mr. Ralph P. Creer, on terminal leave in the Army of the United States, in which he has been director of the medical illustration service, Office of the Surgeon General, has been named assistant in charge of motion pictures of the Bureau of Exhibits, a newly created position. Prior to his entry in service Mr. Creer organized the medical illustration service in the cancer research unit of the Veterans Administration, where he is now a consultant in medical illustration and visual aides. Before his work with the Veterans Administration Mr. Creer was director of the photographic department at the Yale University School of Medicine, New Haven. He organized and was first president of the Biological Photographic Association.

Dr. Frode Jensen, who recently completed three years in the Army of the United States, serving mainly in hospitals on the continent and in Engand, has joined the Council on Medical Education and Hospitals as a hospital inspector. Dr. Jensen, who was released from service with the rank of major, was born in Denmark and graduated at Columbia University College of Physicians and Surgeons in 1933.

Dr. Walton Van Winkle Jr., assistant medical director, U. S. Food and Drug Administration, Washington, in charge of new drugs, has been appointed assistant to Dr. Austin E. Smith to serve as secretary to the new Therapeutic Trials Committee, a standing committee of the Council on Pharmacy and Chemistry, effective April 1. Dr. Van Winkle graduated at Stanford University School of Medicine, San Francisco, in 1938. He concluded three years' service as instructor in the department of pharmacology at Stanford when he first joined the Food and Drug Administration as assistant chief of the division of pharmacology in 1942.

Dr. Harold D. Kautz is returning to the staff of the Council on Pharmacy and Chemistry as assistant to the Secretary. Dr. Kautz was a member of the staff prior to his entry in the Army of the United States some four years ago.

Mr. John A. Kovacs has been made an assistant in the office of the Secretary of the Council. Master Sergt. Kovacs received the Legion of Merit "for exceptionally meritorious conduct in the performance of outstanding services" in an administrative capacity in the North African Theater of Operations (The Journal, Dec. 18, 1943, p. 1054). Mr. Kovacs had been a member of the Council staff before he entered the army.

Dr. Harold R. Hennessy, Los Angeles, recently released from service in the medical corps of the army, has joined the staff of the Council on Industrial Health as Assistant Secretary. While in service Dr. Hennessy received the Bronze Star through the Fifteenth U. S. Army for his work with the military government public health program. Prior to his entry into the army he was medical officer with the California State Department of Public Health. Dr. Hennessy graduated at the University of *Minnesota School of Medicine, Minneapolis, in 1930.*

Washington Letter

(From a Special Correspondent)

March 4, 1946.

Hawley Takes Over as Veterans Medical Chief

Serious hospitalization problems faced Major Gen. Paul R. Hawley, who has been acting as medical chief of the Veterans Administration, as he took over today as permanent chief of the agency's Department of Medicine and Surgery. On loan from the Army up to now, he has retired from the Army to become No. 2 man in the Veterans Administration under Gen. Omar N. Bradley. The Hawley-Bradley hospital program calls for construction of hospitals near medical schools where the best doctors and surgeons will be available. Now it is feared that Congress will insist that the agency take over army and navy surplus hospitals instead of building some eighty new ones. Provision for putting up thirty of this total is now at stake in the 1947 independent office appropriation bill, which is awaiting conference. General Hawley estimates that two thirds of his time has been spent listening to pressure groups on and off Capital Hill.

White House Conference on Saving Food

At the request of President Truman, former President Herbert Hoover and twelve other prominent Americans met in Washington last week for a White House conference on how to save food in this country to ease hunger abroad. The President has asked for an "aggressive voluntary program" to prevent waste of food in the United States so that more can be shipped to war torn sections of Europe and Asia. Mr. Hoover expects the European situation to be alleviated when the first harvest is reaped in June. The Secretary of Agriculture is less optimistic, believing that the chief problem is transportation, not supply. Meanwhile millers have launched the flour conservation program.

Utilization of Military Medical Veterans

Brig. Gen. R. W. Bliss, Deputy Surgeon General of the Army, has written to the National Association of Veterans of the Hospital Corps, with headquarters in Washington at 1705 M Street N.W., urging that hospitals and allied veteran agencies wherever possible use the services of former medical department personnel. The association has appealed for ex-navy and coast guard and army medical veterans to register for cost free service in finding jobs in laboratories, hospitals or institutions as aides, technicians, nurses, doctors, dietitians and orderlies Miss Ruth Kirkland, ex-pharmacist's mate, now chief clerk of the group, says that "utilizing military medical veterans, as suggested by General Bliss, will help in putting the nation on a higher health standard."

Hospital Center Bill Under Consideration

Representative McMillan, chairman of the House District Committee, reports that a new plan is being studied to finance the 1,500 bed modern hospital center proposed for the nation's capital. It would involve deeding Emergency, Garfield and Episcopal hospitals to the government in return for full federal financing. Garfield Hospital would be razed and its 10 acre site used for the new center. The sum of $5,000,000 would be granted for improvements in Providence, Columbia, Children's and Sibley hospitals. The current market value of the land on which the three hospitals to go to the government are located is about $3,000,000, or one fifth of the cost of the proposed $15,000,000 center.

Opposition to Antivivisection Bill

Dr. Alfred Blalock of Johns Hopkins testified against the Lemke antivivisection bill, joining army, navy and private physicians who are fighting the measure, which would prohibit medical experimentation on dogs in Washington Said Dr. Blalock to the House District Judiciary Subcommittee "I defy any surgeon in this country to attempt this operation until he has performed it on one or two animals. I don't think he would have the temerity to try it on any one's child without that" Dr. Blalock said "this work would not have been done" without the dogs, because their blood vessels are large enough to work with and observe. It was pointed out that treatment of water on the brain, lung removal, the use of blood plasma for shock and other life saving operative procedures would never have come about without research on dogs. Brig. Gen. Stanhope Bayne-Jones of the Army, Capt. E. J. Hackenson, director of research at the Bethesda Medical Center, and Dr. Frederick Brady of the U. S. Public Health Service testified how research on dogs had contributed to treatment of such tropical diseases as malaria and filariasis.

Hearings on Mental Health Institute

Public hearings will start March 6 before the Senate subcommittee on health and education on the bill to set up a mental health research institute in the U. S. Public Health Service. The bill would authorize grants for training mental health experts and demonstrations of mental care programs The bill was introduced in the Senate last June by Senator Pepper, Democrat of Florida. Co-sponsors are Senators Thomas, Democrat of Utah, Tunnell, Democrat of Delaware, Hill, Democrat of Alabama, Murray, Democrat of Montana, La Follette, Progressive of Wisconsin, and Aiken, Republican of Vermont.

Explosion in Operating Room

When a tank of nitrous oxide exploded in an operating room at Providence Hospital because of a faulty valve, it shattered the skylight and showered 8 persons, including an anesthetized patient, with heavy plate glass. Dr. Robert Coffey had just completed an appendectomy on the woman patient.

Coming Medical Meetings

Aero Medical Association, Chicago, April 7-9. Dr. David S. Brachman, 1016 Dime Building, Detroit 26, Secretary.

Alabama, Medical Association of the State of, Birmingham, April 16-18. Dr. Douglas L. Cannon, 519 Dexter Ave., Montgomery 4, Secretary.

Alaska Territorial Medical Association, Juneau, March 11-13. Dr. William P. Blanton, Juneau, Secretary.

American Association of Anatomists, Cleveland, April 4-6. Dr. Eliot R. Clark, University of Pennsylvania School of Medicine, Philadelphia 4, Secretary.

American Pediatric Society, Skytop, Pa., May 1-3. Dr. Hugh McCulloch, 325 N Euclid Ave., St. Louis 8, Secretary.

American Physiological Society, Atlantic City, March 11-15. Dr. Wallace O. Fenn, 260 Crittenden Blvd., Rochester 7, New York, Secretary.

American Society for Experimental Pathology, Atlantic City, March 11-15. Dr. Harry P Smith, 630 W. 168th St, New York 32, Secretary.

American Society for Pharmacology and Experimental Therapeutics, Atlantic City, March 11-15. Dr. Raymond N. Bieter, University of Minnesota Medical School, Minneapolis, Secretary.

American Surgical Association, Hot Springs, Va., April 2-4. Dr. Warfield M. Firor, Johns Hopkins Hospital, Baltimore 5, Secretary.

Arizona State Medical Association, Phoenix, May 2-3. Dr. Frank J. Milloy, 112 N. Central Ave., Phoenix, Secretary.

Arkansas Medical Society, Little Rock, April 14-15. Dr. W. R. Brooksher, 602 Garrison Ave, Fort Smith, Secretary.

Central States Dermatological Society, Detroit, April 27. Dr. Clarence E. Reyner, Henry Ford Hospital, Detroit, Secretary.

Connecticut State Medical Society, Hartford, May 1-3. Dr. Creighton Barker, 258 Church St, New Haven 10, Secretary.

Dallas Southern Clinical Society, Dallas, Texas, March 18-21 Dr. John G. Young, 1719 Pacific Avenue, Dallas 1, Director of Clinics

Federation of American Societies for Experimental Biology, Atlantic City, March 11-15. Dr. D. R. Hooker, 19 West Chase Street, Baltimore 1, Secretary.

Florida Medical Association, Jacksonville, April 22-24. Dr. Robert B McIver, P. O. Box 1018, Jacksonville, Secretary.

Iowa State Medical Society, Des Moines, April 17-19. Dr. John C. Parsons, 406 Sixth Ave, Des Moines 9, Secretary

Kansas Medical Society, Wichita, April 22-25 Dr. F. R Croson, 112 W. Sixth St., Topeka, Secretary.

Maryland, Medical and Chirurgical Faculty of, Baltimore, April 23-24 Dr W Houston Toulson, 1211 Cathedral St, Baltimore [illegible], Secretary

Medical Library Association, New Haven, Conn, March 25-27. Miss Frida Pliefke, 2000 Medical Arts Bldg, Minneapolis 2, Secretary.

Missouri State Medical Association, St Louis, March 24-26 Dr. Ralph L Thompson, 634 N. Grand Blvd, St Louis 3, Secretary.

New Orleans Graduate Medical Assembly, New Orleans, April 1-4 Dr Joseph S D'Antoni, 1430 Tulane Ave, New Orleans 13, Secretary

New York, Medical Society of the State of, New York, April 29-May [illegible] Dr Walter P Anderton, 292 Madison Ave, New York 17, Secretary

North Carolina, Medical Society of the State of, Pinehurst, May 1-3 Dr Roscoe D McMillan, P O Box 232, Red Springs, Secretary

Postgraduate Institute of the Philadelphia County Medical Society, Philadelphia, April 9-12. Dr. George P. Muller, [illegible] S 21st St, Philadelphia, Director.

South Carolina Medical Association, Greenville, April [illegible]-May 2 Dr Julian P. Price, 105 W. Cheves St, Florence, Secretary

Southeastern Surgical Congress, Memphis, Tenn, March 11-13. Dr. Benjamin T. Beasley, 45 Edgewood Ave S E, Atlanta 3, Georgia, Secretary

Tennessee State Medical Association, Knoxville, April 9-11. Dr. W. M Hardy, 706 Church Street, Nashville, Secretary.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest such as relate to society activities, new hospitals, education and public health)

DISTRICT OF COLUMBIA

New Director of Venereal Disease.—Lieut Col Samuel R Taggart was recently appointed director of the venereal disease bureau of the District Health Department, filling the vacancy that occurred when Dr Frederick G Gillick resigned last August to accept a position with the U S Public Health Service in Philadelphia (The Journal, Sept 1, 1945, p 81) During the interim Dr Benjamin D Chinn, director of clinical work for the bureau, has been acting chief

FLORIDA

Physician Honored.—Dr. Benjamin H Minchew, Waycross, Ga , past president of the Georgia Medical Association, has been awarded the Baynard Knight cup by the Waycross Kiwanis Club, the award being made annually to the Kiwanian contributing the most distinguished service to the community, it was reported January 6

IDAHO

Licensure Applicants Must be Graduates of Approved Schools—The Idaho State Board of Medical Examiners at a meeting January 15 amended its regulations to provide that after February 15 all applicants must be graduates of an approved medical school of the United States or Canada, as designated in the latest revision by the Council on Medical Education and Hospitals of the American Medical Association A new regulation was adopted stipulating that hereafter no applicant will be allowed to write the examination unless his credentials are in due form to be examined by the board one day before the beginning of the examination and further, that all applicants must be present on the appointed date of the examination of their credentials for a personal interview Applicants appearing late for the interview will not be permitted to write the examination

ILLINOIS

New Executive Director for Handicapped Children—Howard E M Miller, M A , Bloomington has been appointed executive director of the Illinois Commission for Handicapped Children, effective March 1 The commission, with offices at 211 West Wacker Drive, Chicago, is the official state agency responsible for promoting and coordinating both public and private health, welfare, education and vocational services for children who are physically or mentally handicapped

Chicago

The Jaffé Lecture.—The second Richard H Jaffe Lecture will be delivered April 9 at the Palmer House by Dr Wilton M Krogman, associate professor of anatomy and physical anthropology, University of Chicago School of Medicine, on "The Skeleton in Forensic Medicine"

Raymond Allen Goes to Washington.—Dr Raymond B Allen, executive dean of the Chicago colleges of the University of Illinois and dean of the medical school, has resigned to become president of the University of Washington Seattle, effective September 1 Dr Allen graduated at the University of Minnesota Medical School, Minneapolis, in 1928 Before joining Illinois he was dean of the Wayne University College of Medicine Detroit He became executive dean of the Chicago colleges of the university in 1939 and dean of the medical school in 1943

INDIANA

Changes in Health Personnel—Dr Thomas E Conner, Freetown, has been appointed health officer of Jackson county, also jail and county farm physician, succeeding Dr Daniel J Cummings, Brownstown, whose term expired Dr James M Burk Decatur, resigned recently as secretary of the Decatur board of health, in which capacity he had served since 1943

Charles Myers Acting City Health Commissioner—Dr Charles W Myers, superintendent of the Indianapolis City Hospital, has been appointed acting city health commissioner pending the appointment of a permanent successor to the late Dr Herman G Morgan He will continue at the hospital and be assisted in the health administration by Dr Gerald F Kempf director of the bureau of preventive medicine

University News.—Dr John L Arbogast, LaFayette, recently released from service in the army, has been named director of the clinical laboratory of the Indiana University Medical Center to succeed Dr Clyde G Culbertson, Indianapolis who resigned to become a member of the research staff of Eli Lilly and Company Mr Edmund J Shea, recently released from the army, has returned to the center as assistant administrator

Branch Offices Set Up for State Health Department.—Under a decentralization program, five branch offices of the Indiana State Board of Health have been designated under a new zone setup Each branch office will serve approximately eighteen counties, thereby giving coverage to all ninety-two counties of the state Units have been created in Columbus, Valparaiso, Fort Wayne, Washington and Terre Haute The six state board of health district health departments which previously served thirty-three counties in southern Indiana will be discontinued, as these areas will now be served by branch offices

Requirements for Osteopathic Physicians.—The council of the Indiana State Medical Association has requested the state board of medical registration to adopt a resolution concerning the granting of licenses to all osteopathic physicians The legislature in its 1945 session passed a law providing for the practice of medicine by osteopathic physicians under the same terms and conditions as apply to graduates of approved medical colleges In its requests, the council urges

> that each and every applicant for a certificate to practice osteopathy, medicine surgery and obstetrics be required to have successfully passed an examination in materia medica in a medical school approved by the Indiana State Board of Medical Registration and Examination said examination having been successfully passed as a prerequisite to graduation from said approved medical school before the applicant is admitted to examination before the Indiana State Board of Medical Registration and Examination

LOUISIANA

New Professor of Ophthalmology.—Dr George M Haik, New Orleans, has been made professor of ophthalmology at the Louisiana State University Medical School, New Orleans, succeeding the late Dr Theodore J Dimitry

Dr. Kandle Joins Public Health Association—Dr. Roscoe P Kandle, Monroe, has resigned as director of the division of local health services of the Louisiana State Board of Health to become field director of the American Public Health Association, with headquarters in New York

University News—The medical research division of Sharp and Dohme, Inc , Glenolden, Pa , has given $5,000 to the Tulane University of Louisiana School of Medicine, New Orleans, to be used in the continuation of research on sulfathalidine and tyrothricin, under the direction of Dr Chapman G Johnson, assistant professor of gynecology and obstetrics

Graduate Medical Assembly—The ninth annual meeting of the New Orleans Graduate Medical Assembly will be held at the Municipal Auditorium April 1-4 with the following guest speakers among others

Dr William D Stroud, Philadelphia, Cardiology
Dr Frederick D Weidman Philadelphia, Dermatology
Dr Clifford J Barborka Chicago, Gastroenterology
Dr Goodrich C Schauffler, Portland Ore , Gynecology
Dr Russell L Haden Cleveland, Medicine
Dr George T Harrell Jr Winston Salem N C , Medicine
Dr Edgar F Fincher, Atlanta, Ga , Neuropsychiatry
To be announced Obstetrics
Dr James W White, New York, Ophthalmology
Dr Earl D McBride Oklahoma City, Orthopedic Surgery
Dr Oliver L Van Alyea, Chicago Otolaryngology
Dr Robert A Moore, St Louis, Pathology
Dr Arild E Hansen, Galveston Pediatrics
Col James B Brown, Valley Forge General Hospital, Phoenixville, Pa , Surgery
Dr Oscar T Clagett, Rochester Surgery
Dr Elmer Belt, Los Angeles, Urology

Additional information may be obtained from Dr Joseph S D'Antoni, secretary, Room 105, 1430 Tulane Avenue, New Orleans 13

MARYLAND

The Hideyo Noguchi Lectureship—"Charles Edouard Brown-Sequard, a Nineteenth Century Neurologist and Endocrinologist,' was the general subject of the eighth Hideyo Noguchi Lectureship, sponsored by the Johns Hopkins University School of Medicine, Baltimore, and the Institute of the History of Medicine, Baltimore James M D Olmsted Ph D , professor of physiology, University of California Medical School Berkeley, gave the series The first lecture was presented on February 19 on "Mauritian Student and Free Lance Investigator in Paris, the second February 20 on "His Neurological Practice and American Professorships," and the third February 21 on 'In the Chair of Medicine at the College de France' The Noguchi Lectureship was established through a gift of $10,000 given in 1929 by Dr Emanuel Libman, New York

Laboratory for Neuropsychiatric Research.—The Alfred Ullman Laboratory for Neuro-Psychiatric Research is announced for the new name of the laboratory for neuroendocrine research of the surgical division of Sinai Hospital, established in 1935. The new laboratory is the result of the extension and the rebuilding of the old laboratory. The old unit was created through the sponsorship of Dr. Alfred Ullman, Baltimore, and was assigned to Dr. Hyman S. Rubenstein, Baltimore, for research, instruments and supplies being acquired by funds personally supplied by Drs. Ullman and Rubenstein. The newly extended laboratory was made possible through gifts from friends and patients of both physicians and it was decided to name the laboratory in honor of Dr. Ullman, recently retired chief of surgery at the Sinai Hospital, and at the same time to identify it with the principal interest of Dr. Rubenstein, director of neuropsychiatric research. Among other equipment, the laboratory has been furnished with facilities for neuropathologic investigation, a psychogalvanometer, electrical apparatus for peripheral nerve testing and the electroencephalograph. Arrangements have been made to include secretarial and technical assistance. In addition, a research fellowship has also been established.

MICHIGAN

The Beaumont Lecture.—Dr. Robert E. Gross, Boston, will deliver the Beaumont Lecture in the Wayne County Medical Society April 8 on "Surgical Treatment for Abnormalities of the Heart and Great Vessels."

People's Community Hospital Authority Formed.—At a recent meeting of the board of directors of the People's Community Hospital, Inc., it was decided to transfer the assets of the group to the newly created People's Community Hospital Authority, now a municipal corporation. The new group will devote its entire time toward furthering permanent hospital facilities for western Wayne County. The People's Community Hospital in western Wayne County was opened in December 1944, the realization of a plan to make available beds at the Eloise Hospital and Infirmary, Eloise, for patients of private physicians (The Journal, Dec. 30, 1944, p. 1159).

Course in Medical Economics.—The Michigan State Medical Society and the medical schools of the University of Michigan, Ann Arbor, and Wayne University, Detroit, are cooperating in a course on medical economics. The first was opened at Wayne University College of Medicine, March 7, by Dr. Ray S. Morrish, Flint, president of the Michigan State Medical Society. Among his topics were medical societies and what they represent, covering organization, reasons and advantages of joining, how to join, importance of medical meetings and of young men taking part, medical economics and compliance with registration laws. Dr. L. Fernald Foster, Bay City, secretary of the state society, will discuss, March 14, medical public relations, medical legislation and accomplishments. Dr. Wilfrid Haughey, Battle Creek, editor of the *Journal of the Michigan State Medical Society*, will speak, March 21, on Michigan plan for medical service, service to veterans, rural and urban medicine, and voluntary vs. compulsory plans. A similar course will open at the University of Michigan some time in April.

MINNESOTA

Personal.—Dr. Alloys F. Branton, director of the Willmar Clinic, Willmar, and executive secretary of the Minnesota Hospital Association, recently resigned both these positions to become administrator of the Baroness Erlanger Hospital, Chattanooga.

New Industrial Hygiene Head.—George S. Michaelson, chief engineer of the division of industrial health, Minnesota Department of Health, has been named acting director of the division. Dr. Leslie W. Foker, Minneapolis, resigned December 1 as director of the division to enter private practice in the industrial field, according to the *Industrial Hygiene Newsletter*.

Tuberculosis Control Certificate Awarded.—On Dec. 11, 1945 Northfield, the first school system in the United States to qualify, was awarded a tuberculosis control certificate by the American School Health Association. One certificate was given to the Northfield School System, and individual certificates went to Northfield Junior and Senior High School, Longfellow Grade School, Washington Grade School and Rosary Catholic School. Since the first award, announcement has been made of similar awards in other countries.

Special Teaching Assistantships.—Drs. Robert A. Aldrich, Rochester, and Clifford G. Grulee Jr., Evanston, Ill., have been appointed to special teaching assistantships in pediatrics and Dr. Charles U. Culmer, Duluth, to a similar post in surgery, it was announced by Dr. Harold S. Diehl, dean, University of Minnesota Medical School, Minneapolis. Dr. Aldrich graduated at the Northwestern University Medical School, Chicago, in 1944, Dr. Grulee at Northwestern in 1938 and Dr. Culmer at Northwestern in 1940. The funds to support these special assistantships have been provided by the Rockefeller Foundation as part of its program to aid in the development of selected young men whose preparation for teaching and research posts was interrupted by military service. Additional appointments are under consideration in surgery, in neuropsychiatry and in preventive medicine and public health.

NEW HAMPSHIRE

Changes in Health Personnel.—Dr. Mildred I. A. Chamberlin, acting director of the division of maternal and child health and of the division of crippled children's services, state department of health, has resigned to return to private practice in Hillsboro. Capt. Frederick J. Vintinner has returned to his position with the department as director of the division of industrial hygiene. Mr. Vintinner has been serving with the sanitary corps of the Eighth Service Command.

NEW YORK

Director of Mental Hygiene Named.—Dr. Robert P. Kamble, Mount Carmel, Pa., has been appointed director of the division of mental hygiene in the Westchester County Department of Health. He will organize and direct new mental hygiene clinics of the health department.

Emery Dennis Joins Winthrop Company.—Emery W. Dennis, Ph.D., chairman of the departments of bacteriology since 1931 and parasitology since 1935, School of Medicine, American University of Beirut, Lebanon, has been appointed associate director of the biologic division and head of the chemotherapy laboratory of the research laboratories of Winthrop Chemical Company, with offices in Rensselaer. Dr. Dennis received his Ph.D. at the University of California in 1931. From 1935 to 1943 he was associate professor of bacteriology and became professor of bacteriology and parasitology in 1943. During 1934 and 1935 he was in the United States as Rockefeller research fellow in bacteriology at Harvard Medical School.

Compulsory Reporting of Legal Blindness.—All cases of legal blindness in New York must be reported to the commission for the blind of the State Department of Social Welfare in accordance with a recent amendment to the act creating the New York State Commission for the Blind. It is now the duty of every health and social agency, attending or consulting physician or nurse to report to the state commission for the blind, in writing, the name, age and residence of persons who are blind within the definition of blindness and to furnish such additional information as the commission shall request for registration or prevention of blindness. The law supplements the mandated responsibility of the commission for the blind, section 8774, title 24, chapter 3 of the unconsolidated laws to maintain a complete register of the blind in the state of New York which shall describe the condition, cause of blindness, capacity for education and industrial training of each, with such other facts as may seem to the commission to be of value. Data as required by the commission for the blind will further the state's effort to prevent blindness through a comprehensive knowledge of the facts relative to the causes of blindness. This information will also aid in the earlier recognition and detection of cases for which remedial measures for restoration of vision are still possible. Likewise those who may desire the services of the commission for the blind will be benefited through acquaintance with the opportunities available to which they are entitled. Legal blindness is defined as total blindness or impaired vision of not more than 20/200 visual acuity in the better eye and for whom a diagnosis and medical findings show that vision cannot be improved to better than 20/200 or who has loss of vision due wholly or in part to impairment of field vision or to other factors which affect the usefulness of vision to a like degree. Apparent blindness should also be reported even though not based on an eye examination.

New York City

Sam Parker Named Director of Psychiatry.—Dr. Sam Parker, Brooklyn, who has been an alienist in the department of hospitals since 1929, has been appointed director of psychiatry in charge of all psychiatric services in the department. The position has been vacant since the resignation of Dr. Karl N. Bowman (The Journal, Sept. 27, 1941). Dr. Parker graduated at University of California Medical School, Berkeley, in 1913. He will continue as director of the psychiatric service at Kings County Hospital.

Associate Director Named for Speech Hospital.—Dr. Lyman G. Richards, Boston, recently released from service in the navy with the rank of commander, has been appointed associate medical director of the National Hospital for Speech, Disorders, 61 Irving Place. In announcing the appointment, Dr. James S. Greene, medical director of the institution, reported that in 1945, its twenty-ninth year of operation, a total of 3,893 patients registered at the institution, coming from all sections of the United States and Canada and Central and South America.

Committee Named to Choose New Health Commissioner.—A special committee of medical authorities has been formed to recommend a new city health commissioner to succeed Dr. Ernest L. Stebbins, who has resigned to become dean of Johns Hopkins University School of Hygiene and Public Health, Baltimore (THE JOURNAL, Oct. 10, 1945, p. 57). Members of the committee consist of Dr. Thomas Parran, Washington, D. C., surgeon general of the U. S. Public Health Service; Dr. Edward S. Godfrey Jr., Albany, New York State health commissioner; Dr. George Baehr, president of the New York Academy of Medicine; Dr. Wilson G. Smillie, chairman of the public health committee of the New York County Medical Society, and Homer Folks, philanthropist. The committee was formed at the suggestion of Dr. Stebbins, who recently received the thirteenth annual Lincoln Award, presented by the students of the Abraham Lincoln High School for distinguished service to the city. Dr. Stebbins accepted the award in the name of his staff and of every one else affiliated with the department of health. In his speech of acceptance he said that he was happy to see children express their interest in health, as evidenced by the award to him.

Frederick Hoffman Dies.—Frederick Ludwig Hoffman, LL.D., statistician, died in San Diego February 24, aged 80. Dr. Hoffman was born in Germany on May 2, 1865. He came to the United States when he was 19. He subsequently became associated with the Metropolitan Life Insurance Company and the Life Insurance Company of Virginia and served as consulting statistician of the Prudential Insurance Company of America from 1894 until 1935, when he retired at the age of 70. Dr. Hoffman wrote surveys of tuberculosis, cancer, public health, nutrition, malaria, suicide, homicide and various problems of longevity. He held memberships in many medical societies, including the German Cancer Research Society. He was a charter member of the National Tuberculosis Association, director of the American Public Health Association and the American Cancer Society and a member of the National Safety Council. He was a prolific contributor of articles, brochures and books covering a broad range of medical subjects dealing with his various evaluations. In 1911 Tulane University of Louisiana, New Orleans, bestowed on him the honorary degree of doctor of laws. In 1934, with the consent of the Prudential Insurance Company, he presented to the cancer research laboratories of the University of Pennsylvania Graduate School of Medicine, Philadelphia, his library on the subject. In 1943 he was presented in absentia the Clement Cleveland Award. Dr. Howard C. Taylor, in his acceptance address for Dr. Hoffman, credited him with the founding of the American Cancer Society.

NORTH CAROLINA

Changes in Health Personnel.—Dr. Hector H. Henry has been named venereal disease control officer for the city of Charlotte.——Dr. William K. McDowell, Tarboro, has resigned as health officer of Halifax County.

Dr. Morehead to Direct Cancer Program.—Dr. Robert P. Morehead, associate professor of pathology and director of the department, Bowman Gray School of Medicine of Wake Forest College, Winston-Salem, has been appointed educational director of the North Carolina division of the field army of the American Cancer Society.

Dr. Davis Resigns From Industrial Hygiene Division.—Dr. Charles B. Davis Jr., Wilmington, has resigned as director of the division of industrial hygiene of the North Carolina State Board of Health, effective February 1. Newspaper reports indicate that Dr. Davis would return to private practice in Wilmington.

OHIO

Tuberculosis Hospital Association Formed.—The Ohio Tuberculosis Hospital Association was organized Dec. 15, 1945 to set up proposed standards for hospital care. Dr. Oren A. Beatty, Mansfield, superintendent of the Richland County Tuberculosis Sanatorium, is chairman and Dr. William L. Potts, Columbus, of the Franklin County Sanatorium is secretary.

Personal.—Dr. Roy H. Clunk, Massillon, was recently elected president of the Massillon school board.——Dr. Arthur M. Culler, Dayton, has been appointed associate professor of ophthalmology at the Ohio State University College of Medicine, Columbus.——Dr. Donald E. Hale, Butte, Mont., who for the past three years has been in charge of anesthesia at the U. S. Naval Hospital in Philadelphia, has been appointed anesthesiologist at the Cleveland Clinic.

Appointments at Cincinnati.—Dr. Burr N. Carter, recently assistant to the chief surgical consultant in the office of the Surgeon General, Washington, D. C., with the rank of colonel, was named professor of surgery at the University of Cincinnati College of Medicine, succeeding the late Dr. Mont R. Reid. Dr. Albert B. Sabin was promoted from associate professor to full professor of research pediatrics at the school. Joseph L. Schwind, Ph.D., associate professor of anatomy, Albany Medical College, has been named chairman of the department of anatomy, succeeding Dr. Edward F. Malone, resigned.

PENNSYLVANIA

Philadelphia

Personal.—Dr. John W. Crosson, associate medical director of the Medical Research Division of Sharp and Dohme, Inc., has been appointed medical director.

Class of 1911 to Hold Reunion.—The thirty-fifth reunion of the Medical Class of 1911, University of Pennsylvania School of Medicine, will be held May 14 at the Pine Valley Golf Club, Clementon, N. J. Dr. Wilbur H. Haines, 255 South Seventeenth Street, is secretary.

Society News.—Dr. Carlos Santos, Lisbon, Portugal, addressed a special meeting of the Philadelphia Roentgen Ray Society, January 17. *Philadelphia Medicine* reported that Dr. Santos presented a new type of stereoscopic fluoroscopy and a brief analysis of the fundamentals in stereoscopic vision.

Alpha Omega Alpha Lecture.—Dr Eugene M. Landis, George Higginson professor of physiology, Harvard Medical School, Boston, gave the annual Alpha Omega Alpha Lecture at Jefferson Medical College, January 16. His subject was "Venous Pressure and Cardiac Failure in the Laboratory and Clinic."

Postgraduate Institute.—The tenth annual Postgraduate Institute of the Philadelphia County Medical Society will be held at the Bellevue-Stratford Hotel, April 9-12, on the subject of "Progress in Medicine." There will be the usual technical and scientific exhibits. Registration fee for nonmembers of the society is $5. Medical officers are admitted free. The director is Dr. George P. Muller, 301 South 21st Street, Philadelphia 3.

New Professor of Surgery.—Dr. John H. Gibbon Jr., assistant professor of surgery, University of Pennsylvania School of Medicine, has been appointed professor of surgery and director of surgical research at the Jefferson Medical College. He will succeed Dr. George P. Muller, Grace Revere Osler professor of surgery, who will retire at the end of the current school term in March. Dr. Gibbon is the son of Dr. John H. Gibbon, emeritus professor of surgery at Jefferson.

Jefferson Rearranges Obstetric Program.—Dr. Thaddeus L. Montgomery, professor of obstetrics and gynecology and head of the department at Temple University School of Medicine and Hospital, has been appointed to a similar position at Jefferson Medical College. He will succeed Dr. Norris W. Vaux, whose retirement becomes effective at the end of the current school term in March. Dr. Montgomery will devote his major teaching to obstetrics but will continue his practice and participation in gynecology. Coincidental with the announcement of Dr. Montgomery's appointment was one stating that the department of gynecology and the department of obstetrics at the Jefferson Medical College and Hospital will be combined in one department with Dr. Lewis C. Scheffey, professor of gynecology since 1940, as head of the department, professor of obstetrics and gynecology, and director of the division of gynecology. The amalgamation will permit the most effective cooperation in the teaching and practice of obstetrics and gynecology.

SOUTH CAROLINA

Former State Health Officer Honored.—The Columbia Medical Society at its January meeting presented Dr. James A. Hayne, Columbia, former state health officer, with a silver pitcher and tray for his nearly thirty-five years of service in public health work in the state. Dr. Hayne, who became state health officer of South Carolina in 1911, retired in 1944 to become public health education director for the department (THE JOURNAL, May 6, 1944, p. 73). Dr. Hayne is a former president of the Columbia Medical Society and also of the South Carolina Medical Association.

TEXAS

Dr. Cary Honored.—Dr Edward H. Cary, Dallas, on February 21 was presented with the Linz Award, given by Linz Brothers to the "outstanding citizen of Dallas" Dr Cary was cited for his activities as a medical educator and principally for his work as founder and director of the Southwestern Medical Foundation The *Times Herald* is sponsor of the award, which is donated annually by Linz Brothers It is a silver shield on a mahogany base and carries the inscription "for the high ideals and noble aims, from which your splendid work has resulted in greatest benefit to the community of Dallas, this presentation is made by Linz Brothers" Dr Cary, as president of the board of trustees of the Southwestern Medical Foundation, was responsible for the establishment of the Southwestern Medical College He graduated at Bellevue Hospital Medical College, New York, in 1898 From 1902 until 1943, when it moved to Houston, he was professor of ophthalmology and otolaryngology and head of the department at Baylor University College of Medicine, serving as dean from 1903 to 1920 He served as member of the board of trustees of the American Medical Association from 1925 to 1929 and was president of the Association in 1932

Activities at Texas Medical Branch.—Morris Pollard, D V M, formerly of Bellevue, Md, has been appointed assistant professor of preventive medicine and public health to take charge of teaching and research in virus disease at the University of Texas Medical Branch, Galveston Dr Pollard organized and directed the virus laboratory of the Eighth Service Command of the army The National Foundation for Infantile Paralysis, Inc, has granted $3 500 for the support of the work of Ardzroony A Packchanian, Ph D, associate professor of bacteriology and director of the laboratory of microbiology at the university The grant is made to assist in the development of an appropriate small animal host for poliomyelitis virus The John and Mary R Markle Foundation has made a grant of $4 000 to aid the studies on the chemotherapy of malaria under the direction of Dr Wendell D Gingrich of the laboratories of bacteriology and parasitology at the university The John and Mary R Markle Foundation of New York has given a grant of $6,750 to support the studies on rickettsial diseases under the direction of Dr Ludwik Anigstein, associate professor of tropical medicine, and Russell W Strandtmann, Ph D, assistant professor of preventive medicine at the university The Winthrop Chemical Company of New York has made a grant for the study of new anesthesia under the direction of George A Emerson, Ph D, professor of pharmacology at the university. Cancer research at the university under the direction of Wilbur A Selle, Ph D, professor of physiology, has received a grant from the International Cancer Research Foundation, Philadelphia

WEST VIRGINA

Quarantinable Diseases.—Only five communicable diseases are quarantinable in West Virginia under revised regulations adopted by the Public Health Council at a meeting held at Charleston, January 7 Diphtheria, smallpox, epidemic typhus (louse borne), plague and cholera are still classed as quarantinable, but placarding is required only for smallpox, cholera and plague Previously measles, meningococcic meningitis, poliomyelitis, scarlet fever and whooping cough have been quarantinable For other communicable diseases only isolation of the patient is required, and child contacts are to be excluded from school as indicated on the chart of the "Common Communicable Diseases" recently prepared for distribution by the state health department The new regulations were approved by the council of the West Virginia State Medical Association at a meeting held in October 1945, and the Public Health Council has fixed July 1, 1946 as the official effective date The state health department has suggested that all local health departments adopt the new regulations immediately so that ground work may be laid before they actually become law This is necessary because all regulations of the Public Health Council must be advertised locally before they can be officially put into effect A new communicable disease code patterned closely after the American Public Health Association's manual on "The Control of Communicable Diseases" was also adopted by the Public Health Council This action was also recommended by the council of the state medical association While pellagra is no longer reportable, the following have been added to the list of reportable diseases

Epidemic diarrhea of the newborn
Favus
Food infections (salmonellosis)
Food poisoning (staphylococcus and botulinus)
Granuloma inguinale
Infectious keratoconjunctivitis
Lymphogranuloma venereum
Rat bite fever
Relapsing fever
Rheumatic fever
Puerperal infections
Typhus
Weil's disease
Glanders
Acute infectious hepatitis
Pneumonia (all type)

GENERAL

Appointments to Rockefeller Institute.—The board of scientific directors of the Rockefeller Institute for Medical Research announces the appointment of David P C Lloyd Ph D, New Haven, as associate member Dr Reginald M Archibald has been appointed associate and James A Baker, Ph D has been promoted from assistant to associate, Cynthia H Pierce, Ph D, and James R Weisiger, Ph D, have been appointed assistants, all of New York

New Administrative Officer for Hard of Hearing—Mr Harry P Wareham, Rochester, N Y, for many years identified with campaigns for community chests in various cities and formerly executive vice president of the National War Fund, has been named executive vice president of the American Society for the Hard of Hearing, effective March 1 In his new position Mr Wareham will direct the expansion program planned by the society

Hamilton Goss Ansley ⊕ Decatur, Ga.; University of Georgia Medical Department, Augusta, 1928; past president of the DeKalb County Medical Society; on the staff of the Emory University (Ga.) Hospital; died December 16, aged 43, of cerebral hemorrhage.

Melvin Leighton Battles, Norwalk, Ohio; Cleveland Homeopathic Medical College, 1904; member of the American Medical Association; served during World War I; in 1938 retired from the National Guard with the rank of major; died November 27, aged 66.

Louis Bernstein ⊕ Pittsburgh; University of Pittsburgh School of Medicine, 1923; formerly on the staff of the Veterans Administration Facility in Aspinwall; died in the Presbyterian Hospital November 24, aged 45, of coronary occlusion.

Leslie Carr Bishop, Wichita, Kan.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1903; member of the American Medical Association; on the staffs of the Wichita and St. Joseph hospitals; consultant at the Veterans Administration Facility; died in Altadena, Calif., January 6, aged 63, of heart disease.

William N. Boerstler, Stow, Ohio; Western Reserve University Medical Department, Cleveland, 1883; died November 30, aged 89, of senility.

Oliver Diehl ⊕ Medical Director, Captain, U. S. Navy, retired, Bethayres, Pa.; Jefferson Medical College of Philadelphia, 1879; entered the U. S. Navy in July 1882; served in the Spanish-American War, Boxer Rebellion and World War I; retired July 7, 1918 for incapacity resulting from an incident of service; died in Wyncote December 16, aged 89, of a fractured hip and uremia.

Thomas Samuel Finney, Wichita, Kan.; Johns Hopkins University School of Medicine, Baltimore, 1919; member of the American Medical Association; on the staffs of St. Joseph and Wichita hospitals; died January 29, aged 52, of cardiac decompensation and cerebral hemorrhage.

James Siebert Gamble, Lincolnton, N. C.; Medical College of Virginia, Richmond, 1943; superintendent of the Reeves Gamble Hospital and local surgeon for the Seaboard and Southern Railways; died near the Charlotte airport November 4, aged 27, when his private plane crashed.

Thomas A. Guillory, Groesbeck, Texas; Kentucky School of Medicine, Louisville, 1908; member of the American Medical Association; died in Oakdale, La., November 7, aged 63.

Pugh Haynes, Woodlawn, Tenn.; University of Louisville (Ky.) Medical Department, 1884; died November 20, aged 85.

Emil Benjamin Isgreen, Salt Lake City; Rush Medical College, Chicago, 1897; member of the American Medical Association; honorary member of the Utah State Medical Association; on the staff of the Dr. W. H. Groves Latter-Day Saints Hospital, where he died November 25, aged 79, of coronary and cerebral arteriosclerosis.

John Dillard Jacobs, Atlanta, Ga.; University of Nashville (Tenn.) Medical Department, 1898; formerly professor of hygiene and physiology at his alma mater, where he served as secretary and treasurer; died in the Halifax District Hospital, Daytona Beach, Fla., October 17, aged 71.

Robert John James, Los Angeles; Minneapolis College of Physicians and Surgeons, medical department of Hamline University, 1899; on the staffs of the Golden State and Methodist hospitals; died November 30, aged 73.

Ray Walter Karras ⊕ Lake City, Fla.; Wisconsin College of Physicians and Surgeons, Milwaukee, 1912; member of the California Medical Association; served on the staffs of various

Veterans Administration facilities; major, medical corps, Army of the United States, not on active duty; died November 9, aged 57.

Maurice I. Klein, East Orange, N. J.; Baltimore University School of Medicine, 1902; formerly affiliated with the Beth Israel Hospital in Newark; died in the Memorial Hospital, New York, November 21, aged 63, of heart disease.

Albert Knooihuizen, Holland, Mich.; Detroit College of Medicine, 1895; died November 17, aged 81.

Alonzo E. Mack ⊕ Glendale, Calif.; John A. Creighton Medical College, Omaha, 1896; formerly professor of obstetrics at his alma mater; died November 20, aged 75.

Edward McCarthy ⊕ Richmond, Va.; Medical College of Virginia, Richmond, 1881; died November 28, aged 86, of a fractured hip and uremia.

James Albert McComb ⊕ Lebanon, Mo.; Beaumont Hospital Medical College, St. Louis, 1887; on the staff of the Wallace Hospital; president of the public library board; for many years president of the State Bank of Lebanon and chairman of the board of directors at the time of his death on November 15, aged 82.

Gilbert Copson McCormick ⊕ Kansas City, Mo.; Illinois Medical College, Chicago, 1909; served during World War I; major, medical reserve corps, U. S. Army, not on active duty; died in the Menorah Hospital November 21, aged 71, of cerebral hemorrhage.

John Francis McDonald, Hillsboro, Texas; University of Texas School of Medicine, Galveston, 1912; member of the American Medical Association; served during World War I; major in the medical corps of the National Guard not on active duty; died November 18, aged 64, of coronary occlusion.

Walter McDowell ⊕ Evansville, Ind.; Indiana University School of Medicine, Indianapolis, 1929; interned at St. Luke's Hospital in Jacksonville, Fla.; on the staffs of the Welborn-Walker and Protestant Deaconess hospitals; began active duty as a first lieutenant in the medical corps, Army of the United States, in July 1942 and relieved from active duty in November 1942; died November 27, aged 40, of coronary thrombosis.

John Joseph McKenna, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1905; associate professor of roentgenology at his alma mater; served overseas as major in the medical corps of the U. S. Army during World War I; on the staff of the Hahnemann Hospital, where he died November 25, aged 72, of aleukemic leukemia.

William E. Messenger, Independence, Mo.; College of Physicians and Surgeons, Keokuk, Iowa, 1887; died November 17, aged 83.

William Henry Morrison, Springfield, Mass.; Baltimore Medical College, 1905; member of the American Medical Association; died November 22, aged 65, of coronary thrombosis and hypertensive heart disease.

William Ralph Needelman ⊕ Portland, Maine; Yale University School of Medicine, New Haven, 1923; served during World War I; commissioned a first lieutenant in the 240th Coast Artillery, Maine National Guard, in 1937, being called to active duty in September 1940 with the rank of captain; discharged a year later because of ill health; member of the staff at the local induction station since its inception; formerly county medical examiner; on the staff of the Mercy Hospital, where he died November 22, aged 51, of heart disease.

Samuel Arthur Nichols ⊕ Clarksville, Md.; Baltimore Medical College, 1897; past president of the Medical and Chirurgical Faculty of Maryland, Howard County Medical Society and the Maryland, Virginia and District of Columbia Medical Society; affiliated with the Montgomery County General Hospital, Olney, and the Maryland General Hospital in Baltimore; died November 2, aged 75, of coronary thrombosis.

Alfred John Nixon, Taunton, Mass.; Boston University School of Medicine, 1894; died recently aged 80, of arteriosclerosis.

Arthur H. Northrup ⊕ Clearwater, Fla.; Medical College of Indiana, Indianapolis, 1904; member of the Indiana State Medical Association; died November 5, aged 70, of cerebral hemorrhage.

Aage Emanuel Olsen, Ann Arbor, Mich.; Detroit College of Medicine and Surgery, 1926; member of the American Medical Association and the New Mexico Medical Society; at one time Danish vice counsel for Michigan; died November 4, aged 46, of coronary thrombosis.

Mercer Cranor Parrott ⊕ Kinston, N. C.; Tulane University of Louisiana School of Medicine, New Orleans, 1917; fellow of the American College of Surgeons; chief surgeon and medical director of the Parrott Memorial Hospital; director of the First Citizens Bank; died November 17, aged 51, of coronary occlusion.

Irvin N. Paul, Perry, Iowa; the Hahnemann Medical College and Hospital, Chicago, 1885; died November 30, aged 86, of hypostatic pneumonia.

Robert Ernest Perdue, Norwalk, Conn.; Starling Medical College, Columbus, 1895; member of the American Medical Association; for many years health officer of Norwalk; died in the Norwalk Hospital recently, aged 70.

Victor Nathaniel Peterson ⊕ St. Paul; University of Minnesota College of Medicine and Surgery, Minneapolis, 1906; past president of St. Paul Surgical Society; died in the Bethesda Hospital November 28, aged 66, of carcinoma of the stomach.

Rocco Joseph Petrucelli ⊕ Meriden, Conn.; Columbia University College of Physicians and Surgeons, New York, 1934; diplomate of the National Board of Medical Examiners; interned at the United Hospital in Port Chester, N. Y.; chairman of the board of health; physician in parochial schools; died in the Memorial Hospital, New York, November 27, aged 36.

Daniel Ward Philo, Fremont, Ohio; Physio-Medical College of Indiana, Indianapolis, 1901; Toledo Medical College, 1906; served during the Spanish-American War and World War I; died in a hospital at Miami, Fla., November 29, aged 72.

William Joseph Pulley ⊕ New York; Bellevue Hospital Medical College, New York, 1891; formerly clinical professor of medicine at the University and Bellevue Hospital Medical College, where he served as medical superintendent of the college clinic; consulting physician at the Riverside Hospital; died November 16, aged 76, of coronary occlusion.

Ernest Marion Ragsdale, Columbia, Tenn.; Vanderbilt University School of Medicine, Nashville, 1901; member of the American Medical Association; past president of the Maury County Medical Society; for many years resident physician for the Columbia Military Academy; died November 9, aged 65, of cerebral hemorrhage.

James Linton Rentfro ⊕ Brownsville, Texas; Louisville Medical College, 1907; in 1944 honored at a banquet given by the Matamoros Medical Association, Tamaulipas, Mexico, in recognition of his work among the Latin American people on both sides of the Rio Grande; on the staff of the Mercy Hospital; died November 11, aged 60, of coronary sclerosis.

George G. Richardson, Marion, Ind.; Medical College of Indiana, Indianapolis, 1905; member of the American Medical Association; served as county health officer; on the staff of the Marion General Hospital; died November 8, aged 64, of coronary thrombosis.

Thomas Richmond ⊕ Kansas City, Kan.; University Medical College of Kansas City, Mo., 1897; past president of the Wyandotte County Medical Society, serving as its treasurer for many years; served overseas during World War I; on the staffs of the Bethany, Providence and St. Margaret's hospitals; died November 4, aged 73, of coronary thrombosis.

Stonewall Jackson Rollow, Clarksville, Tenn.; University of Nashville Medical Department and Vanderbilt University School of Medicine, Nashville, 1887; served during World War I; died in the Veterans Administration Facility, Marion, November 26, aged 80, of heart disease.

J. H. Eugene Rosamond, Memphis, Tenn.; Louisville Medical College, 1902; specialist certified by the American Board of Pediatrics; member of the American Pediatric Society; fellow of the American College of Physicians; past president of the Tennessee Pediatric Society; at one time member of the council for the Southern Medical Association; died December 12, aged 65.

Douglas Rothschild, Detroit; Detroit College of Medicine, 1907; died November 1, aged 60, of carcinoma of the throat.

Maurice Shapiro ⊕ Bayonne, N. J.; University and Bellevue Hospital Medical College, New York, 1910; past president of the Hudson County Medical Society; formerly city physician and school physician; served as secretary of the board of directors and chief of clinics at Bayonne Hospital; formerly assistant attending dermatologist at the Bellevue Hospital in New York; consulting dermatologist at the Margaret Hague Maternity Hospital in Jersey City; died November 30, aged 57, of coronary occlusion and diabetes mellitus.

George Shorkley ⊕ Mount Vernon, Wash.; Hahnemann Medical College and Hospital of Philadelphia, 1899; served in the Spanish-American War, on the Mexican border and during World War I; on the staff of the Mount Vernon General Hospital; died November 30, aged 74, of coronary thrombosis.

Edwin F. Smith, Lodi, Calif.; Ohio Medical University, Columbus, 1896; died November 27, aged 75.

David Henderson Sprague, Central Valley, N. Y.; University of the City of New York Medical Department, New York, 1886; died November 25 of chronic bronchitis.

Charles William Stratton, Lee, Mass.; Albany (N. Y.) Medical College, 1905; member of the American Medical Association; died November 6, aged 69.

Henry Arthur Swan ⊕ Abilene, Texas; Baylor University College of Medicine, Dallas, 1914; died recently, aged 58.

John M. Triplett, Chapman, Neb.; Lincoln Medical College of Cotner University, 1909; chairman of the board of health; died November 4, aged 78, of arteriosclerosis.

George Washington Upton, Sherman, Maine; Dartmouth Medical School, Hanover, N. H., 1888; member of the American Medical Association; past president of the Aroostook County Medical Society; honorary member of the Maine Medical Association and in June 1937 was presented with its fifty-year service medal; died in the Madigan Memorial Hospital, Houlton, November 23, aged 80.

Walter Volke, Chicago; University of Chicago School of Medicine, 1939; interned at the Englewood Hospital; died in the Albert Merritt Billings Hospital October 5, aged 37, of coronary occlusion.

Alva Harding Warren ⊕ Malden, Mass.; Harvard Medical School, Boston, 1900; member of the New England Roentgen Ray Society and the American College of Radiology; specialist certified by the American Board of Radiology, Inc.; died November 19, aged 71, of pulmonary embolism.

Ossie Alexander Weatherly, Bluefield, W. Va.; Baltimore Medical College, 1909; member of the American Medical Association; medical examiner for the Norfolk and Western Railway Company; died November 27, aged 67, of coronary thrombosis.

Arthur Jay White, Scranton, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1923; member of the American Medical Association; formerly assistant superintendent of the Farview State Hospital, Waymart; died November 21, aged 55.

Charles Alphons Wingerter ⊕ Wheeling, W. Va.; Bellevue Hospital Medical College, New York, 1894; in 1910 member of the House of Delegates of the American Medical Association; past president of the West Virginia State Medical Association, of which he had been an honorary member; served during World War I; member of the board of trustees and member of the staff of the Wheeling Hospital, where he died November 2, aged 79, of cerebral thrombosis.

De'Laniel L. Yost, Fairmont, W. Va.; Indiana Eclectic Medical College, Indianapolis, 1889; died January 17, aged 84.

Capt. Allan Emmert Markowitz, M. C., A. U. S., 1916-1944

Capt. Manning Gunter, M. C., A. U. S., 1911-1945

Lieut. Carl L. Mango, M. C., A. U. S., 1907-1944

Ellen Alfieda Wallace ⊕ Concord, N. H.; Woman's Medical College of the New York Infirmary for Women and Children, New York, 1885; president emeritus of the New Hampshire Memorial Hospital, where she died November 2, aged 92, of cerebral thrombosis.

John Perry Young ⊕ Chester, S. C.; University of Maryland School of Medicine, Baltimore, 1894; Spanish-American War veteran; on the staff of the Pryor Hospital; died in North Charleston November 29, aged 75, of pneumonia and nephritis.

KILLED IN ACTION

Allan Emmert Markowitz, Abilene, Texas; University of Texas Faculty of Medicine, Galveston, 1939; interned at the City Hospital in Cleveland; served a residency at the Bradford Memorial Hospital for Babies in Dallas; began active duty as a first lieutenant in the medical reserve corps of the U. S. Army on July 1, 1941; promoted to captain; killed in action in the North African area Feb. 6, 1944, aged 27.

Manning Gunter ⊕ Globe, Ariz.; Columbia University College of Physicians and Surgeons, New York, 1938; born in Tucson, Ariz., on May 18, 1911; interned at the New York City Hospital in Welfare Island, New York; began active duty as a first lieutenant in the medical corps, Army of the United States, on May 13, 1942; served in Attu, landing with the first 200 troops; served with Seventh Medical Battalion and Seventh Division through all their campaigns in South Pacific, Leyte and Okinawa; promoted to captain; received Purple Heart and Presidential citation for merit; awarded the Bronze Star Medal "for heroic achievement in connection with military operations against the enemy on Nov. 25, 1944" and the Silver Star "for gallantry in action on May 5, 1945"; killed in action in the Pacific area May 5, 1945, aged 33.

Carl Louis Mango, Erie, Pa.; Temple University School of Medicine, Philadelphia, 1937; interned at the York Hospital in York and the Elizabeth General Hospital and Dispensary in Elizabeth, N. J.; began active duty in the medical reserve corps of the Army of the United States as a first lieutenant on March 15, 1941; killed in action in the Philippine Islands Dec. 14, 1944, aged 37, while a prisoner of war of the Japanese government

Coordination of Special Hospitals for the Treatment of Cancer

In order to place its exceptional resources for treatment, teaching and research at the disposal of the patients and staff of other hospitals, and also to obtain a larger number of cases of the less common forms of cancer, the Royal Cancer Hospital has organized a plan for cooperation with London hospitals devoted to other specialties, such as diseases of the chest, eye, ear, nose and throat, gastrointestinal tract and nervous system. Patients referred by a cooperating hospital will be examined by a physician, surgeon, radiotherapist and clinical research assistant. The main lines of treatment will be outlined and the resources of the entire group of hospitals will be available for the patient. Surgical treatment will usually be carried out at the cooperating hospitals, but patients can be freely transferred for surgery, radiotherapy or chemotherapy. Cooperation has been further increased by the appointment of members of the staff of some of the special hospitals to the staff and medical committee of the cancer hospital and the converse. A cooperating hospitals committee has been set up under the chairmanship of Lord Horder to coordinate the cancer work in the group of hospitals and to give advice with regard to its future expansion. The number of new cases seen by the services has already passed 2,000 annually, which corresponds to the normal incidence of cancer in a population of 2,000,000. An important feature of the service is that it has no local limits but is designed to deal with all forms of cancer including the most rare which are selected for treatment at the specialized hospitals.

Epidemic of Virus B Influenza

An epidemic of influenza has been prevalent in Great Britain for a number of weeks. The weekly records of deaths from the disease have reached the highest level in two years. For the week ended January 26 there were 273 deaths in 126 large cities and 35 deaths in London. As a rule the attacks are mild and not attended by any serious complications. Serologic tests indicate that this epidemic is due to virus B influenza, which has not previously been incriminated in any widespread epidemic, though sporadic cases were found in 1939 and in a minor outbreak in 1943.

Retropubic Prostatectomy

At the Urological Section of the Royal Society of Medicine Mr. Terence Millin opened a discussion on retropubic prostatectomy, a new operative technic devised by him which was recently described in the *Lancet*. The operation has attracted much attention, since it appears to be an improvement on the many operations for removal of the enlarged prostate. It has the great advantage of being extravesicular, avoiding suprapubic drainage. It takes a relatively short time, does not involve or injure any organ, and has a singularly low mortality. In the 20 cases in which Mr. Millin has operated, there has not been a fatality. As all the obstructing tissue is removed, recurrence of obstruction is obviated.

A median 2½ to 3 inch suprapubic incision is made. The recti are separated and kept so by a modified Harris retractor; the posterior blade of the retractor presses the bladder upward and backward. The veins on the anterior and lateral aspects of the prostate are ligated. With a diathermy knife a transverse incision, convex downward, is made through the prevesical fascia and true prostatic capsule. The false capsule is exposed and an inverted V incision is carried down to the adenoma. The V shaped flap is elevated, and with curved dissecting scissors the lower margins of the lateral lobes of the enlarged prostate and, when present, the middle lobe are freed digitally from below upward. Enucleation is easily performed.

The comments of the urologists were favorable to the new operation. The president of the section, Mr. A. Wilfrid Adams, commended the technic of Mr. Millin, which removed the obstruction to bladder outflow directly. Mr. E. W. Riches praised the principles of direct approach and of enucleation from below but pointed out that the approach was through a vascular area, so that the operation was a bloody one. There was general agreement that the operation was not one for the inexperienced operator.

Assistance to Mental Patients—Discussion of a New Law

Mental patients in occupied France were left in asylums to die from starvation and epidemics. The death rate rose 30 to 50 per cent. Immediately after the liberation psychiatric problems and especially the problem of caring for mental patients demanded immediate attention. Their care is still dictated by the law of 1838, which prescribes the confinement of acute and chronic mental patients in asylums.

Since the recognition and development of mental hygiene, there have been in France some wards for psychopathic patients, and in some large cities there are special hospitals and homes, such as the Henri Roussel Hospital, organized by Dr. Toulouse, one of the most prominent defenders of mental hygiene. In 1937 the name "maison d'aliénés" was changed to "psychiatric hospital" without any modification of the methods of treatment.

At a meeting of psychiatrists in which numerous specialists from all over France took part, a resolution for the abolition of the law of 1838 was unanimously adopted. They proposed to replace the "lunatic asylums" with a district (departmental) hospital system containing a security ward for dangerous patients with reeducation homes for alcoholic addicts and other toxicomaniacs and an organization for the placement of patients in families in the country and with medicopedagogic institutions for defective children. The difficulties are technical, as France cannot immediately create a sufficient number of psychiatric hospitals. There is also a shortage of the necessary psychiatrists. The first step is to establish psychiatric wards in the existing hospitals.

A discussion among psychiatrists is now taking place as to the law which should be substituted for the law of 1838. There are two main ideas to be noted among the several submitted to the Ministry of Public Health. The first, worked out by M. D. Abely and a group of psychiatrists, recommends the admission of every mental patient to the psychiatric hospital without any formality. These patients will be given two papers by the attending physician: an application for admission without diagnosis and a sealed letter for the psychiatrist containing the presumable diagnosis. Hospitalized patients will be given complete or restricted liberty, according to their condition. As to the management of their property, the legal forms will be either the appointment of a counselor as provisory administrator or of a trustee. The second plan has been advocated by Dr. Heyer, who in a recent article published in the *Médecin français* proposes that mental patients, with the exception of dangerous cases, should not be subjects of any particular legal measure and should be treated and granted every liberty consistent with their condition. Heyer is relying on his experiences as a psychiatrist practicing for twenty-five years and as official physician to the special infirmary of the Paris prefecture of police. He has found in his private practice that 2 to 3 patients out of 10 must be interned. In his ward at the special infirmary

9 out of 10 must be interned because of insufficient observation. He points to the example of Denmark, where only 2 per cent of mental patients are interned. The author insists that the use of private homes does not increase the danger of mercenary sequestration, so much feared by public opinion; unfortunately, private homes are accessible only to wealthy patients. According to the author the psychiatrist should not be concerned with administrative or legal questions but concentrate on modern treatment in the psychiatric wards which he proposes to organize in each district hospital. The new law will be incorporated in the new constitution, which is now being prepared by the Constitutional Assembly.

High Death Rate of Nurslings

Levesque and Bastin have called attention to the high death rate of babies under 1 year of age. This fact was also emphasized by the statistician Moine in his work entitled "Infancy in Danger," which indicated congenital weakness and premature birth as main causes of the high rate of infant mortality. The frequency of premature births has been pointed out by various authors, among them Dufour, medical inspector of the Bouches-du-Rhône district, who read a paper on this subject recently at a meeting of the congress for the Advancement of Science.

THE NETHERLANDS

(From Our Regular Correspondent)

AMSTERDAM, Jan. 31, 1945.

War Against Children

Infant mortality was exceptionally low in the prewar Netherlands. Individual hygiene and medical care must be credited for this progress during the last forty years. The Germans thoroughly altered this and performed a planned campaign against 20,000 Jewish children. Amsterdam pediatricians have medically evaluated the results of this cruelty. The first stage in the action was deportation to pooling camps. There an average of 200 mothers with infants were crowded into barracks without sanitation or ventilation. In smaller rooms 60 infants with a variety of diseases or infections were confined. Personnel, all prisoners, had to sleep and live in the same rooms. Unwashed towels were dried in the same room where "lavatories" stood, which were mortuary and kitchen at the same time. In the ward were children with whooping cough, measles, scarlet fever, malignant dysentery, pneumonia, nasopharyngitis and otitis media. They were starved rather than fed with food exposed to flies, coming from uncovered sick children, several of them in the same bed, without blankets or sheets. This was a major experiment to see what would happen after exposure to instead of isolation from various diseases prevalent among children. Efficient medical aid was forbidden, and even the mothers were prohibited from attending their dying little ones. As a result of this remarkable experiment most children began to be ill with dysentery of the Flexner type and to contract all the other diseases in varying sequence. Yet the death rate seemed too low; suddenly all the children were packed into trains, despite pyrexia up to 104 F. with pneumonia, even a 5 day old baby of 3 pounds (1,350 Gm.), and deported to Poland, where those who arrived living were murdered in the gas chambers. Enteric disease was the most frequent disease in the camps (doctors were not allowed to investigate for differential diagnosis) and otitis with mastoiditis.

Among the children of Amsterdam the death rate began to mount in 1944, owing to enteritis and to starvation of babies or to overfeeding with inadequate food. Mortality reached five times the normal level. Exact information is not available as to the nature of the enteric disease, although it might be related to epidemics that raged or still exist in western Europe. Liver damage was rather constant and a relation to a plague of flies apparent.

Other diseases of children were dystrophies due to starvation, but edema was exceptional in comparison with the adults. Serious war sequels are tuberculosis of children in increased frequency and congenital syphilis, reappearing now, whereas it had been almost extinct in the prewar Netherlands.

BELGIUM

(From Our Regular Correspondent)

Feb. 11, 1946.

International Committee of Military Medicine and Pharmacy

A meeting of the International Committee of Military Medicine and Pharmacy was held in Brussels Nov. 19 and 20, 1945. The International Committee accepted the invitation of the Swiss Federal Government to hold the eleventh congress in Switzerland in 1947. The following subjects were on the program of this congress: 1. Methods of resuscitation of the injured; reporters, England, France and Jugoslavia. 2. General review of modern procedures for prophylaxis of epidemic diseases in armies; reporters, the United States, Switzerland and Great Britain. 3. Modern methods of evacuation of the wounded and sick: indications and contraindications; reporters, Canada, Russia and Poland. 4. Participation of military physicians in the moral and physical welfare of the soldier; reporters, Belgium, France and Switzerland. 5. Comparative study of methods and apparatus for the determination of the hydrogen ion concentration with a view of their employment in the pharmaceutical laboratories of armies; reporters, Switzerland, France and Brazil. The following resolution was sent to the International Committee of the Red Cross in Geneva: "The International Committee of Military Medicine and Pharmacy meeting on Nov. 19, 1945 in Brussels begs the International Committee of the Red Cross to examine the question of medical personnel of armies protected by the Geneva Convention who are still in captivity and to use its great influence in their interest. It appears indeed opportune to consider with a purely disinterested and humanitarian aim the release of physicians and medical personnel who remain prisoners, who have been prisoners for a long time and who have not failed in their soldierly duties and honor."

The Health Control of Workers

A regent's decree will soon be published which regulates medical service in industrial enterprises. Beginning January 1 all enterprises (industrial, commercial and public service) must provide at their own expense medical service consisting of a complete examination at the time of hiring (analyses and roentgenologic examinations) and a periodic examination of the working personnel. The examination of adolescents is to take place every year and is to be carried out in the same manner as at the time of first employment. For adult workers examinations at variable intervals are permissible, depending on the type of employment. The interval may vary from one month to two years. The physician must make out an individual report after each examination. He has at his disposal for this purpose special and not very complicated forms. A copy of this report comprising the medical observations and especially the diagnosis is sent to the provincial health inspector. The employer is not to know the nature of the disorder detected in a member of his personnel. The physician must likewise keep a health record which must accompany the worker throughout his life as a worker. The employer has free choice of a medical examiner. He can, however, be put under obligation to change him at the request of the worker's physician in cases in which the medical examiner "does not observe the instructions concerning the health control of the workers or refuses to furnish the administration with information which is necessary to assure the observation of the prescriptions of the present decree."

MEXICO

(From Our Regular Correspondent)

Jan. 5, 1946.

Eradication of Smallpox in Mexico

During the conquest of Mexico smallpox was introduced by a Negro slave named Francisco Eguía, who came with the forces of Panfilo de Narvaez sent from Cuba to fight and punish Hernán Cortés. Since that time Mexico has paid a heavy toll. The "cocoliztli," as it was called by the Aztecs, has caused millions of deaths. Baron Alejandro von Humboldt stated that the disease killed more Indians than the cannons and muskets of the Spaniards. According to this author the number of deaths caused by smallpox amounted to two millions during the period of 1555-1556 in the territory occupied now by the Federal District and the states of Mexico, Michoacan, Puebla and Oaxaca. Subsequently several local epidemics were registered in the different parts of New Spain. The most important ones were those which occurred in 1763-1769, 1779, 1798, 1814 and 1829. Later, since the introduction of the Jenner vaccine on July 24, 1804 by Dr. Francisco Xavier de Balmis and Dr. Antonino Gutierrez the different governments have been fighting the plague with relative success. During the preceding and present administrations, smallpox has been attacked intensively in such a way that at the present time it is almost absent. In some states such as Yucatán, Campeche, Chiapas, Tabasco and others in the southeast not 1 case has been registered during the last five years.

Mortality Rate for Smallpox in Mexico

Year	*Population (Calculated)*	Number of *Deaths*	Rate per *100,000*
1940	19,759,112	1,341	6.8
1941	20,075,793	2,529	12.6
1942	20,392,473	4,115	20.2
1943	20,709,154	3,738	18.0
1944	21,025,835	2,252	10.8
1945	21,342,516	813	3.8

The mortality rate for smallpox during the last six years in Mexico is given in the accompanying table.

The mortality rate up to November 1945 was 0 to 5 per hundred thousand inhabitants in the Federal District, the territories and twenty-four states, 5.1 to 10 in Nayarit and Jalisco, 20 in the state of Hidalgo and 30 per hundred thousand of population in the state of Guanajuato in the central plateau.

Since the middle of 1945 not a single case of smallpox has been reported in many states, although vaccination was quite difficult in the mountainous regions and native villages. The immunization rate varies from 90 per cent in the urban districts to 60-70 per cent among the rural population. The public health and welfare authorities hope to banish smallpox forever during the first quarter of 1946.

Whooping Cough Immunization

Whooping cough is considered in Mexico a major cause of death of patients over 9 years of age. The disease kills in this country fourteen times more children than diphtheria, seven times more than smallpox, typhoid and syphilis and one and a half times as many as measles and bronchitis. During the four years ended December 1944 Dr. Miguel F. Bustamante, in charge of the Laboratory of Epidemiology and Biostatistics of the Institute of Public Health and Tropical Diseases, carried on a series of experimental immunizations against pertussis, using 7 cc. of Kendrick's vaccine in treating a group of 982 children. Another group of 589 children was used as a control. The environmental, social and living conditions were the same for the two groups. The average age among the children in the immunized group was 19.49 months and in the control group 20.19. The mean duration of the experiment was 21.74 and 21.99 months for each group respectively. The mean number of members per family was 5.3 and 5.2. According to the studies made, the results obtained by Dr. Bustamante and his co-workers were 1.92 person-months attacks per hundred months' experience in the immunized children against 8.66 in the control group, i. e. a difference of 6.74 ± 0.18, which is significant. The rate of attack per year in the first group was 1.8 against 5.8 in the control group. In this experiment the effective protection among vaccinated children was 75 per cent, with an annual attack rate of 2.8 per cent as compared to 5.5 per cent in the second group.

Committee for the Standardization of Laboratory Methods

A meeting was held on January 3, 1946 in the office of the undersecretary of public health and welfare to appoint a committee for the standardization of laboratory procedures. The committee appointed consists of the following section chairmen: Dr. Gustavo Argil, Section of Pathologic Biochemistry; Dr. Ernesto Cervera, director of the Institute of Hygiene, Section of Microbiologic Methods and Technics; Dr. Manuel Martinez Baez, Clinical Pathology; Dr. Ignacio González Guzmán, dean of the National School of Medicine, Hematology; Dr. Tomas G. Perrin, Serology, and Dr. Fernando Ocaranza, chief of the Division of Laboratories, Public Health Laboratories. Dr. Manuel Martínez Baez, Undersecretary of Public Health and Welfare, will act as president.

Courses in the School of Public Health and Hygiene

On December 17 in the Auditorium of the National School of Public Health and Hygiene, the annual ceremony to close the activities of the academic year took place, presided over by Dr. Gustavo Baz, secretary of public health and welfare. The speakers included Dr. Manuel Martínez Baez, undersecretary of public health and welfare, Dr. Angel de la Garza Brito, dean of the National School of Public Health and Hygiene, and Dr. Ernesto Molina of Colombia. Degrees of Master of Public Health were granted to nineteen students (five from Colombia), and certificates of attendance were given to ninety-seven public health nurses, thirty-four sanitary inspectors and nine physicians who attended a short course on malariology.

Marriages

STANLEY H. HOFFMAN, Glenn Dale, Md., to Wave Lieut. (jg) Teresa R. Blumberg of Terre Haute, Ind., in Washington, D. C., December 29.

CHARLES MONROE LANDMESSER, Lakeland, Fla., to Miss Jessie Norwood Jeffers in Florence, S. C., November 3.

EMORY CLIFTON KINDER, Kingstree, S. C., to Mrs. Hilda Whitaker Purse of Chattanooga, Tenn., recently.

CHARLES KENDALL DONEGAN to Miss Margaret Graham Mangum, both of Durham, N. C., January 19.

MELVIN L. PETERS, Cameron, Mo., to Miss Gussie Gearhart of Princeton in Troy, Kan., December 24.

JOHN ALBERT REINECK, Norwalk, Ohio, to Miss Rosemary Brennan of Pacific, Mo., in November.

WAYNE JOHN FENCIL, Monroe, Wis., to Miss Mary Jane Doherty in Milwaukee, December 26.

GEORGE S. KING to Miss Ruth C. Kahler, both of Bay Shore, N. Y., at Great Neck, January 10.

ALBERT H. VOEGELE to Miss Elaine Marie Schiller, both of Mansfield, Ohio, December 1.

EVANS WILLIAM PERNOKIS, Chicago, to Miss Olga Stuart of New York, December 30.

SOL Z. DRAZNIN, Chicago, to Miss Esther Bishop of Green Bay, Wis., January 3.

HERMAN L. KRETSCHMER to Mrs. Marion Ellen Hicks, both of Chicago, March 3.

FREDERICK G. GAENSLEN, Milwaukee, to Miss Jeanne Sweet of Madison recently.

Correspondence

REFRIGERATION FOR CRUSHED FINGER

To the Editor:—In THE JOURNAL, Dec. 29, 1945, page 1296, an adverse reply is given to a navy lieutenant who inquired concerning his application of ice to a finger which had been crushed and nearly amputated. The theory contained in the reply seems fallacious, as cold preserves tissue by reducing its metabolism and diminishing the need for either arterial or venous circulation. It is also contrary to the unanimous experience in major surgery, such as the English adoption of refrigeration for crush injury of limbs, and the preservation of circulation or development of collateral circulation during weeks of icing (Mock; Nachlas; Crossman; Ottaway and Foote; literature by Allen, F. M.: *Am. J. Surg.* **68**:170 [May] 1945). The only 2 minor cases which I have encountered have been successful, as follows:

An Italian laborer aged 64 had his thumb nearly severed at the interphalangeal joint, the distal phalanx hanging only by a thin shred of skin. The doctor who saw him for me in my absence inquired if he should complete the amputation, but I advised by telephone to place the hand in a basin of cracked ice. Four hours later the parts were united by suture without drainage. The thumb was kept in ice for twenty-four hours and then changed to ice bags, which were gradually withdrawn during four days. The result was a complete functional thumb except for ankylosis of the interphalangeal joint.

A girl aged 5 years had her left ring finger chopped off with a hatchet. The cut was through the middle phalanx, and here also nothing but a thin bridge of skin remained. When I first saw the patient six hours after the accident, the severed part appeared very cyanotic and cadaveric. After suture, the finger was packed in ice for thirty-six hours by a unique method. The mother cut a hole in a rubber fountain syringe, so that the child's hand could be inserted and surrounded with ice, while the melting water drained out through the tubing into a pail on the floor. During the following days the important principle of gradual elevation of temperature was applied by using ice bags which were successively withdrawn. The outcome has been a perfect finger except for limitation of motion in the distal phalanx, which observers expect to be lessened by exercise and time.

It appeared improbable that the digit in either of these cases could have been saved by customary measures. As it is unreasonable to expect invariable success with any method, it seems proper to ask the lieutenant's critics whether any of them have any personal experience with reduced temperature or whether they know of any instance of deleterious effects from its proper use.

LYMAN WEEKS CROSSMAN, M.D., New York.

MEDICAL SURPLUS PROPERTY

To the Editor:—For your information the following: Being on terminal leave after five years of active duty and in need of equipment for my office, I took THE JOURNAL at its word and very optimistically made a visit to the Los Angeles branches of the Smaller War Plants Corporation, the War Assets Corporation, the Office of Surplus Property RFC et al. with the following results:

Page 282 of THE JOURNAL for February 2 gave the regional office as Pacific Mutual Building, Los Angeles. Arrival there disclosed a palatial setup with high powered appearing executives, as far as the eye could reach, ensconced behind heavy plate glass and mahogany. They could be seen only by appointment, I was informed by one of the young lady buffers holding forth at the mahogany barrier. On learning my business, however, she informed me that THE JOURNAL was 100 per cent wrong and that it would be necessary for me to go to another building in another part of town which specialized in surplus medical equipment. This building was situated on Seventh Street near Los Angeles Avenue.

This information was a lift, because that was just what I was looking for, the boys who specialized in medical equipment, just like THE JOURNAL said.

Now this office was a letdown after viewing the splendor of the other one, but there were long lines of veterans waiting to be seen and, I thought, now we are getting some place. As I got closer to the front of the line, though, my spirits sagged as I noticed those turned away from the desk sadly shaking their heads and muttering to themselves as they filed past. I consoled myself with the thought that these poor misguided unfortunates were no doubt in the wrong place trying to buy silly things like locomotives, amphibious adding machines and bulldozers; they should know that they ought to be up at the swank joint in the Pacific Mutual Building. I was now all goose pimples; I was only third man from the front, which gave me a chance to observe the gal behind the counter. She looked harassed and bedraggled, but it was almost noon and no doubt the poor girl was weak from hunger. But when my turn came she was still breathing, so I took a chance.

Now I hate to tell you this, Mr. Editor, but this gal said she didn't know where THE JOURNAL got its information, but there was no such thing as a listing of surplus medical equipment and, what's more, she doubted if there ever would be one. In spite of her weakened condition she was not unsympathetic, and she lowered her voice to tell me that this was the way it always was and so I gathered that it was just the same old runaround being given veterans everywhere. She did suggest that I could return that afternoon when a group class would be held on how to make an application, and I could then apply for the items I might be interested in. Then some day if they ever got those items they would notify me within the next few months.

I started to say "how the h—— can I make application when I don't know what you have for sale," but I thought better of it and decided to go back to the plush carpeted office in the Pacific Mutual Building, where the girls were better looking, and buy myself a tank or a small used destroyer at least.

JAY G. WANNER, Lieutenant Colonel, M. C., A. U. S.

CONTROLLED FOLLOW-UP STUDIES IN PSYCHIATRY

To the Editor:—The method of controlled follow-up studies is not utilized sufficiently in medical science. If it were, the literature would be burdened with far less unsubstantiated therapeutic claims and other so-called discoveries. Psychiatry, for many years backward as compared to the progress made in other medical specialties, is now utilizing this method more frequently. Such a study made by a New York commission to evaluate the effects of insulin shock therapy in schizophrenia was discussed in a recent issue of THE JOURNAL (Feb. 10, 1945, p. 334). Recent studies on convulsive shock therapy in the affective psychoses (manic-depressive and involutional melancholia) reveal important data not previously known, which would not have become available except by the utilization of controls (Ziskind, Eugene; Somerfeld-Ziskind, Esther, and Ziskind, Louis: Metrazol and Electric Convulsive Therapy of the Affective Psychoses, *Arch. Neurol. & Psychiat.* **53**:212 [March] 1945. Tillotson, K. J., and Sulzbach, Wolfgang: A Comparative Study and Evaluation of Electric Shock Therapy in Depressive States, *Am. J. Psychiat.* **101**:455 [Jan.] 1945).

It is especially important that the control and treated series include cases seen by the same investigators over the same period and under the same conditions since, particularly in the psychiatric field, diagnostic and therapeutic interpretations vary so much from person to person, place to place and time to time, and also since the selection of material often varies. The worst cases are segregated in state hospitals, whereas in private practice mixed degrees of severity are encountered.

In such a control series from the private practice of myself and associates, consisting of 88 treated and 109 untreated patients over a five year period, and contacted subsequently (the follow-up period averaged three and one-fourth years), successfully treated patients recovered in a much shortened period of time (three to six weeks) and the adequately treated patients were prevented from dying from suicide and exhaustion, whereas 12 per cent in the control series did die. It is of more than theoretical interest that, once the fatal cases were excluded from the series, the follow-up showed that just as many of the untreated cases (86 per cent) as the treated cases (88 per cent) automatically went on to recovery of the individual attack, although the duration of the illness was much longer in the untreated cases. Another revelation of the follow-up controlled study was the equality of the number of recurrences in both the treated and untreated cases (18 and 21 per cent respectively), demonstrating that, although the treatments are beneficial in shortening the individual attack of the manic-depressive psychoses, there is no effect on later recurrences. Another follow-up investigation (Tillotson and Sulzbach) on 138 cases of depression revealed a greater recovery rate in the 70 treated than in the 68 untreated cases. Discrepancies in the two studies were more apparent than real, for in the first the controls included many patients whose illness was considered too mild to treat. When correction was made for this factor (comparison restricted to those control cases in which treatment was recommended but refused) and the deceased patients were not excluded from the control series, the increase of individual recoveries in the treated cases approximated the second study.

These reports indicate the value of control follow-up series. Though admittedly difficult and often containing many variable factors, they still constitute the best known approach to evaluation of new therapies. More such studies will lead to refinement of technic and statistical computation, reducing the differences arising from the variable selection of material.

EUGENE ZISKIND, M.D., Los Angeles.

"THE PELLAGRA PROBLEM"

To the Editor:—I have read your editorial on "The Pellagra Problem" (THE JOURNAL, Nov. 24, 1945, p. 874) with great interest. You mention the suggestion by Krehl, Teply, Sarma and Elvehjem (*Science* **101**:489 [May 11] 1945) "that the synthesis of niacin by the intestinal flora may be involved." You do not mention that production and release of nicotinamide by the intestinal flora in man has been shown by myself and my co-workers (Ellinger, P., and Coulson, R. A.: *Biochem. J.* **38**:265 [No. 3] 1944. Ellinger, P.; Coulson, R. A., and Benesch, R.: *Nature* **154**:270 [Aug. 26] 1944. Ellinger, P.; Benesch, R., and Kay, W. W.: *Lancet* **1**:432 [April 7] 1945. Ellinger, P.: *Nature* **155**:319 [March 17] 1945); up to 100 per cent (in the average 60 per cent) of the daily nicotinamide requirements of man can be synthesized by the flora of the intestinal tract; the obvious conclusions concerning the etiology and cure of pellagra have been discussed in the papers mentioned.

I am surprised that your editorial writer had not noticed these papers, which have received publicity in editorials in the *Lancet* and *British Medical Journal* and also one by American workers (Briggs, A. P.; Singal, S. A., and Sydenstricker, V. P.: *J. Nutrition* **29**:331 [May] 1945) in which the same function of the intestinal flora is suggested. In the interest of chronological accuracy I think these omissions should be noted in the pages of THE JOURNAL.

P. ELLINGER,
Lister Institute of Preventive Medicine,
London, S.W. 1.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and the Examining Board in Specialties were published in THE JOURNAL, March 2, page 601.

BOARDS OF MEDICAL EXAMINERS

ALABAMA: Mar. 19-21. Sec. Dr. B. F. Austin, 519 Dexter Ave., Montgomery 4.

ARIZONA: * *Examination.* Phoenix, April 2-3. *Endorsement.* Phoenix, April 6. Sec., Dr. J. H. Patterson, 826 Security Bldg., Phoenix.

ARKANSAS: * *Medical.* Little Rock, June 6-7. Sec., Medical Board of the Arkansas Medical Society, Dr. L. J. Kosminsky, Texarkana. *Eclectic.* Little Rock, June 6. Sec., Dr. C. H. Young, 1415 Main St., Little Rock.

CALIFORNIA: *Written.* Los Angeles, March 11-14. Sec., Dr. Frederick N. Scatena, 1020 N St., Sacramento 14.

COLORADO: * Denver, April 2-5. Final date for filing application is March 18. Sec., Dr. J. B. Davis, 831 Republic Bldg., Denver.

CONNECTICUT: * *Medical. Examination.* New Haven, March 12-13. *Endorsement.* New Haven, March 26. Sec. to the Board, Dr. Creighton Barker, 258 Church St., New Haven. *Homeopathic.* Derby, March 12-13. Sec., Dr. Joseph H. Evans, 1488 Chapel St., New Haven.

DELAWARE: *Examination.* Dover, April 9. *Reciprocity.* Dover, April 16. Sec., Medical Council of Delaware, Dr. J. S. McDaniel, 229 S. State St., Dover.

DISTRICT OF COLUMBIA: * *Reciprocity.* Washington, March 11. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6150 E. Municipal Bldg., Washington 1.

FLORIDA: * Jacksonville, June 24-25. Sec., Dr. Harold D. Van Schaik, 2736 S.W. Seventh Ave., Miami 36.

GEORGIA: Atlanta and Augusta, March 27-28. Sec., State Examining Boards, Mr. R. C. Coleman, 111 State Capitol, Atlanta 3.

HAWAII: Honolulu, July 8-11. Sec., Dr. S. E. Doolittle, 881 S. Hotel St., Honolulu 53.

IDAHO: Boise, July 9. Dir., Bureau of Occupational Licenses, Miss Agnes Barnhart, 355 State Capitol Bldg., Boise.

ILLINOIS: *Examination.* Chicago, April 2-3. *Reciprocity.* Chicago, April 4. Supt. of Registration, Department of Registration & Education, Mr. Philip Harman, Springfield.

INDIANA: Indianapolis, April 25-27. Sec., Board of Medical Registration & Examination, Dr. W. C. Moore, 301 State House, Indianapolis 4.

IOWA: * Iowa City, March 25-27. Dir., Division of Licensure & Registration, Mr. H. W. Grefe, Capitol Bldg., Des Moines 19.

KANSAS: Kansas City, March 12-13. Sec., Board of Medical Registration and Examination, Dr. J. F. Hassig, 905 N. Seventh St., Kansas City 10.

KENTUCKY: Louisville, March 25-27. Sec., State Board of Health, Dr. Philip E. Blackerby, 620 S. Third St., Louisville 2.

MAINE: Portland, March 12-13. Sec., Board of Registration of Medicine, Dr. A. P. Leighton, 192 State St., Portland.

MARYLAND: *Medical.* Baltimore, March 19-22. Sec., Dr. J. T. O'Mara, 1215 Cathedral St., Baltimore 1. *Homeopathic.* Baltimore, June 18-19. Sec., Dr. J. A. Evans, 612 W. 40th St., Baltimore.

MASSACHUSETTS: Boston, March 12-15. Sec., Board of Registration in Medicine, Dr. H. Q. Gallupe, 413-F State House, Boston.

MICHIGAN: * Detroit, March 26-28. Sec., Board of Registration in Medicine, Dr. J. E. McIntyre, 100 W. Allegan St., Lansing 8.

MISSISSIPPI: June. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson 113.

MONTANA: Helena, April 1-3. Sec., Dr. O. G. Klein, First National Bank Bldg., Helena.

NEBRASKA: * Omaha, March 25-27. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, 1009 State Capitol Bldg., Lincoln 9.

NEW JERSEY: Trenton, June 18-19. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

NEW MEXICO: * Santa Fe, April 8-9. Sec., Dr. LeGrand Ward, 141 Palace Ave., Santa Fe.

NEW YORK: Albany, Buffalo, New York and Syracuse, June 24-27. Sec., Dr. Jacob L. Lochner, Education Bldg., Albany.

NORTH CAROLINA: Raleigh, March 25-28. Act. Sec., Mrs. Louise J. McNeill, 226 Hillsboro St., Raleigh.

NORTH DAKOTA: Grand Forks, July 2-5. Sec., Dr. G. M. Williamson, 4½ S. Third St., Grand Forks.

OHIO: *Examination.* Columbus, March 19-22. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

OKLAHOMA: * Oklahoma City, March 23. Sec., Dr. J. D. Osborn Jr., Frederick.

PENNSYLVANIA: Philadelphia and Pittsburgh, April. Act. Sec., Bureau of Professional Lic[illegible] [illegible]lic Instruction, Mrs. M. G. Steiner, 351 Educ[illegible]

RHODE ISLAND: Providence, April 4-5. Chief, Division of Examiners, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

SOUTH DAKOTA: * Pierre, July 16-17. Sec., Medical Licensure, State Board of Health, Dr. Gilbert Cottam, Capitol Bldg., Pierre.

TENNESSEE: * Memphis and Nashville, March 27-29. Sec., Dr. H. W. Qualls, 130 Madison Ave., Memphis 3.

TEXAS: Austin, March 27-29. Sec., Dr. T. J. Crowe, 918-20 Texas Bank Bldg., Dallas 2.

VERMONT: Burlington, March or April. Sec., Dr. F. J. Lawliss, Richford.

VIRGINIA:* Richmond, March 25-28. Sec., Dr. J. W. Preston, 803 Medical Arts Bldg., Roanoke.

WASHINGTON:* Seattle, July 11-12. Sec., Department of Licenses, Miss Nell Adams, Olympia.

WEST VIRGINIA: Charleston, April 1-3. Commissioner, Public Health Council, Dr. John E. Offner, State Capitol, Charleston 5.

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

DISTRICT OF COLUMBIA: Washington, April 22-23. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6150 E. Municipal Bldg., Washington 1.

FLORIDA: Gainesville, June 4. Final date for filing application is May 20. Sec. Dr. J. F. Conn, John B. Stetson University, DeLand.

IOWA: Des Moines, April 9. Dir., Division of Licensure & Registration, Mr. H. W. Grefe, Capitol Bldg., Des Moines 19.

MICHIGAN: Ann Arbor and Detroit, May 10-11. Sec., Miss Eloise LeBeau, 101 N. Walnut St., Lansing.

MINNESOTA: Minneapolis, April 2-3. Sec., Dr. Raymond N. Bieter, 126 Millard Hall, University of Minnesota, Minneapolis 14.

NEBRASKA: Omaha, May 7-8. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, 1009 State Capitol Bldg., Lincoln 9.

SOUTH DAKOTA: Vermillion, March 13-14. Sec., Dr. G. M. Evans, Yankton.

TENNESSEE: Memphis and Nashville, March 25-26. Sec., Dr. O. W. Hyman, 874 Union Ave., Memphis.

WISCONSIN: Madison, April 6. Prof. R. N. Bauer, 152 W. Wisconsin Ave., Milwaukee 3.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: General Release of Primary Cause of Action Held Release of Claim of Intervening Malpractice.—The plaintiff physician filed suit for a declaratory judgment as to the legal effect of a general release which the defendant executed in favor of the Minneapolis Street Railway Company in settlement for injuries received in a street car accident. From a judgment in favor of the physician the defendant appealed to the Supreme Court of Minnesota.

The defendant was injured while alighting from a street car and engaged the plaintiff physician to treat her injuries. Part of the treatment involved the use of an electrical apparatus and defendant claimed she received burns therefrom. In a subsequent action against the street car company, after a verdict in her favor, she entered into a stipulation by the terms of which she released and discharged the street car company "from all claims, demands, actions or causes of action, for all injuries or damages, whether at this time known or unknown, arising or to grow out of the said accident referred to above." In neither the pleading nor trial of that case did the defendant mention any burns she suffered as a result of the plaintiff's negligence. Prior to the termination of her suit against the street car company, the defendant commenced a malpractice action against the plaintiff. After the stipulation in the street car company case was filed, the plaintiff filed an amended answer in the malpractice action to the effect that the release to the street car company released the defendant's whole cause of action, including the claim for malpractice against the plaintiff. Subsequently, by means of various proceedings to which the plaintiff was not a party, the defendant attempted to avoid the effect of her general release. Plaintiff therefore filed this suit for a determination of the rights of the parties.

The Supreme Court said that where one person is injured by the wrong or negligence of another, and the injured person himself is not negligent in the selection of a medical attendant, the wrongdoer is liable for all the proximate results of his own act, although the consequences of the injury would have been less serious than they proved to be if the attendant had exercised proper professional skill and care. The defendant admitted that such was the law but urged that this case was an exception. She argued that since, in the street car case, no claim or mention was made of any burns received during the treatment for her injuries, therefore the only recovery that she made against the street railway company was for the injuries she sustained through the negligence of the company and consequently the release and satisfaction could not possibly have included the injuries for malpractice. She suggests that the basis for the rule set forth by the court is to prevent one person from recovering twice for the same injury, and that in this case no basis for the rule exists since she could not possibly recover for the same injury because she refrained from claiming or proving aggravation of her injuries through malpractice.

The Supreme Court admitted that the defendant presented a plausible argument but pointed out that her general release operated not only in personam on the street car company and its liability but also in rem on her own cause of action. The decisive thing now, said the court, is not whether the plaintiff actually released this defendant, or intended to do so, or got full compensation, but rather and only whether she has discharged her whole cause of action. This, concluded the Supreme Court, she did do. If the instrument is in fact a release, it discharges all parties liable for the injury. If, in such a case as this, it is desired to come to an accommodation with the original wrongdoer, saving to the injured person a cause of action, if any, against the attending physician or surgeon, it may be done by the use of a convenant not to sue. Accordingly the judgment of the trial court in favor of the plaintiff was affirmed.—*Benesh v. Garvais, 20 N. W. (2d) 532 (Minn., 1945).*

Life Insurance: Physical Manifestations of Sunstroke Not Visible Wounds or Contusions.—The plaintiff sued to recover under the double indemnity provisions of a life insurance policy issued to her deceased husband, who died as the result of a sunstroke. From a judgment in her favor the defendant insurance company appealed to the circuit court of appeals, tenth circuit.

The policy provided that

> If the death of the insured . . . results directly and independently of all other causes from bodily injuries effected solely through external, violent and accidental means, . . . and if such accident . . . is evidenced by a visible contusion or wound on the exterior of the body, the sum insured provided on the first page of the attached policy will be doubled.

According to the agreed facts the deceased, shortly before he died, became pale, remarked that he felt a "hot spell or something" coming over him and immediately went to bed. His clothes were wet with perspiration and he complained of smothering to death and of pains in his arms. His face was a pale yellow, his lips were blue and swollen, his eyes were glassy and the pupils dilated, he vomited blood, and hot fluid flowed from his nose. Just before death occurred his "skin had turned blue practically all over his body."

Under established Oklahoma law, the court pointed out, it is well settled that sunstroke is an accident effected solely through external, violent and accidental means. The question is whether or not the facts show a "visible contusion or wound on the exterior of the body." The court pointed out that in many of the cases relied on by the plaintiff the insurance policy required a "visible mark or evidence of injury" or language meaning substantially that. Under such a proviso, said the court, we would have no difficulty in concluding that there were visible marks and evidence of an injury. The insurance policy in question, however, requires a "wound" or "contusion" on the exterior of the body. The words "wounds" and "contusions," concluded the court, have well defined and understood meanings. The commonly understood and accepted meaning of the word "wound" is an injury to a person in which the skin or other membrane is broken, as by violence or surgery. "Contusion" is commonly defined as a bruise affecting subcutaneous tissue without breaking the skin. "Contusion," in its ordinarily accepted meaning, is synonymous with "bruise." It is difficult to think of pallor, perspiration, dilated pupils or a bluish tint to the skin immediately preceding death, said the court of appeals, as either wounds or contusions. To so hold would, in our opinion, do violence to the ordinarily accepted meaning of these terms as they are understood by intelligent persons. Accordingly the judgment in favor of the plaintiff was reversed and the cause remanded with direction to enter judgment in favor of the insurance company.—*Paul Revere Life Insurance Company, Worcester, Mass., v. Stanfield, 151 F. (2d) 776 (1945).*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1936 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Note on Serologic Classification of Streptococci Isolated from Subacute Bacterial Endocarditis. S. M. Wheeler and G. E. Foley.—p. 511.

Syndrome of Bernheim.—Russek and Zohmann present observations on 3 cases of Bernheim's syndrome, 2 of which were diagnosed during life and confirmed at necropsy and 1 discovered on postmortem examination. The diagnosis is suggested when a person with left ventricular hypertrophy shows signs of right heart failure as the first indication of circulatory embarrassment. The "right heart failure" is not due to myocardial weakness but results from obstruction to blood flow through the right ventricle. Dyspnea and other signs of pulmonary congestion are conspicuously absent or minimal until the terminal stage of the disease, when failure of the left ventricle finally supervenes. The circulation time may remain within normal limits for some time while the venous pressure is appreciably elevated. Fluoroscopy may be helpful in demonstrating enlargement of the left ventricle and right auricle with normal size of the other two chambers. The bulging and thickened interventricular septum may influence the electrical axis of the heart and even be responsible for unexpected right axis deviation in cases of left ventricular hypertrophy. The syndrome of Bernheim may occur in any condition causing left ventricular hypertrophy and dilatation.

Traumatic Injury of Heart in Bodily Injuries.—Sigler studied 39 cases of accidental injuries of the body in admissions to the surgical wards of the Coney Island Hospital and in 3 cases from other sources. In 32 of these 42 cases there was demonstrable evidence of some cardiac damage, clinical, electrocardiographic or both. In some cases the damage occurred even if the blow did not affect the chest, provided it was of sufficient severity to result in grave bodily injury. In most cases the damage appeared to be mild and of short duration. Subjective manifestations referable to the heart were trivial or absent. Precordial pain or discomfort and slight dyspnea were the main complaints. The objective manifestations consisted of abnormalities in the heart sounds, the presence of a gallop rhythm, a pericardial friction rub and systolic murmurs in various areas. The findings were transient and occurred in comparatively few cases. The electrocardiographic manifestations consisted of changes in the voltage and appearance of the QRS complex from time to time and some shift in the electrical axis; elevation, rounding with upward concavity and occasional coving of the RT segment, and frequent changes in the T wave from positive to isoelectric and negative and back to positive. In the majority of cases the electrocardiographic changes were nonspecific. In occasional cases they were characteristic of pericardial involvement or of localization of the damage to other specific areas of the heart. Complete recovery took place in nearly all cases in this series. Only 1 case showed permanent damage and in another case the cardiac injury was at least partly responsible for death.

Cardiovascular Manifestations of Neurocirculatory Asthenia.—Friedman studied the cardiovascular manifestations of neurocirculatory asthenia in 50 cases. He found the heart in neurocirculatory asthenia to be normal in size, structure and function at rest and during effort if unaccompanied by emotional activity. Changes in the rate, rhythm and force of cardiac contractions were observed when preceded by or associated with excitation of the sympathetic nervous system. This phenomenon was observed during a natural exacerbation of the syndrome or following the administration of suitable drugs. Evidence was obtained which suggested that the excitation of the sympathetic nervous system, preceding or associated in a causal fashion with the cardiovascular manifestations of neurocirculatory asthenia, resulted from hypothalamic discharge.

Histoplasmosis in Children: Review of Literature, with Report of Case. A. M. Iams, M. M. Tenen and H. F. Flanagan.—p. 229.

Infectivity of Primary Tuberculous Complex of Childhood.—Feldman and Helmholz examined during a six year period lesions of primary pulmonary tuberculosis for the presence of virulent tubercle bacilli in 29 children dying of causes other than tuberculosis. Each specimen was used to inoculate 2 guinea pigs, and the results were observed at necropsy eight weeks later. In only 5 of 29 patients were virulent tubercle bacilli demonstrated. The youngest child in whom virulent tubercle bacilli were found was an infant of 3 months, and the oldest in whom the results were positive was a child of 11 years. If the results of the study of this small series of cases are a true reflection of the state of infectivity of the lesion of the primary complex in children without concomitant tuberculous disease, one may conclude that the tubercle bacilli responsible for the primary lesions of pulmonary tuberculosis of childhood tend in most instances to become avirulent or to disappear.

Early Syphilis Resistant to Penicillin.—Tyson reports a case in which a penile ulcer appeared ten days after intercourse. At the time of examination, two weeks after appearance of the lesion, dark field examination revealed Treponema pallidum. The Kahn test was positive. Treatment consisted of thirty intramuscular injections of 80,000 units of penicillin, or a total of 2,400,000 units over a period of five days. The serologic test remained positive for several weeks and the penile lesion did not heal. An ulcer was still present when the serologic test became negative. When the serologic tests became positive again and secondary lesions appeared, treatment was repeated with 600,000 units of penicillin and eight hours of fever therapy. After this the penile lesion and secondary lesions healed. Spinal fluid examinations for syphilis were negative. It is significant that the patient, aged 24, responded to penicillin plus fever but apparently did not respond to penicillin alone.

Leiomyoma of Terminal Ileum.—p. 666.

Therapeutic Measures in Rheumatic Fever.—Gubner and Szucs analyzed the effects of various therapeutic measures in 150 cases of acute rheumatic fever. The treatments included sodium salicylate and sodium bicarbonate (33 cases), sodium salicylate and ascorbic acid (32 cases), calcium double salt of benzoic acid and succinic acid benzyl ester (55 cases), sulfathiazole (15 cases); penicillin (5 cases) and sodium bicarbonate alone (10 cases). Sulfathiazole, penicillin and sodium bicarbonate alone were without therapeutic effect. Striking difference was not evident in the two groups of patients receiving salicylate other than noteworthy diminution in toxicity in the patients receiving ascorbic acid in place of sodium bicarbonate. Comparison was made between the 65 patients given salicylate and the 55 receiving the succinate compound. The patients receiving the succinate compound and ascorbic acid responded more favorably than did those receiving salicylate. The duration of fever, leukocytosis and accelerated sedimentation rate, and total days of hospitalization were uniformly and significantly abbreviated. Signs of carditis developed in 69 per cent of the salicylate treated patients compared with 19 per cent of the succinate treated ones. Relapses of rheumatic activity occurred in 7 of the salicylate treated patients whereas relapses did not develop in those given succinate. Drug toxicity was noted in 19 per cent of the salicylate treated patients but in only 2 per cent of those receiving the succinate compound. Attention is called to the role of succinic acid as a catalyst in biologic oxidation. Evidence is cited that a widespread interference with various constituents involved in tissue oxidation occurs in rheumatic fever—that is, porphyrinuria, lowering of plasma ascorbic acid and vitamin A levels and changes in glutathione. It is suggested that there is an oxidative inactivation of various enzymes in this disease and that administration of succinates may not only prevent inhibition of succinic dehydrogenase (cytochrome C reductase) but as an active reducing agent may also prevent inactivation of other respiratory enzymes. Calcium and ascorbic acid enhance the activity of succinic dehydrogenase, and the administration of ascorbic acid as well as the calcium salt of the succinic acid compound studied therefore appears to be indicated.

Allergenic Effect of Silica.—Habeeb says that a new factor in silicotic dyspnea has recently come to light, namely bronchospasm. Administration of epinephrine relieves dyspnea and bronchospasm, whereas histamine causes dyspnea and wheezing due to bronchospasm in patients with silicosis. Eosinophilia is generally considered to be part of an allergic response, and, since a high percentage of patients with silicosis have a blood eosinophilia which is proportional to the extent of their disease, it seems safe to conclude that silica dust has allergenic properties. The author discusses such factors as fibrosis, emphysema, bronchospasm, capillary obstruction and dilatation and believes that all play a variable part in the respiratory disability.

Prospect for Future Control of Tuberculosis. J. A. Cremer.—p. 952.

Failure of Vitamin K in Dicumarol Poisoning.—The case presented by Bauerlein indicates that vitamin K in large doses is in some cases without effect on the prothrombin level when it has been seriously affected by the use of dicumarol. A man aged 52, who had been treated for thrombophlebitis of the ankle by ligation of the saphenous vein, was given 100 mg. of dicumarol daily during subsequent painful swelling of the leg. Prothrombin estimations were not done. After thirteen doses of dicumarol the patient reported hematuria. The thrombophlebitis had subsided completely except that the thrombosed vein was still palpable. The patient was given a vitamin K preparation by vein and by mouth for several days, but hematuria persisted and the prothrombin time was prolonged until blood and fresh plasma transfusions were given. Fresh plasma undoubtedly is a good source of prothrombin. Bauerlein concludes that the administration of dicumarol without daily determination of the prothrombin time is an unwise procedure and may result in serious hemorrhage even in the absence of trauma. The tourniquet test becomes positive when the prothrombin time is definitely prolonged by the use of dicumarol. Large doses of vitamin K seemed to be without effect, at least within a six day period, in abolishing the prothrombin deficiency induced by dicumarol in the case observed here. Fresh plasma should be used to combat the hemorrhagic tendency due to dicumarol.

Neuropathologic Problems After Prefrontal Leukotomy.—The material reviewed by Meyer and Beck consists of 7 cases of prefrontal leukotomy and an eighth case in which frontal lobectomy had been carried out on a mentally normal person with a basal meningioma. This last case has proved of great value as a test case for complete severance of fiber connections. In 2 further cases only macroscopic investigation was performed. All the patients who recovered showed little or moderate deterioration. Clinical complications did not interfere with recovery, and the operation itself produced circumscribed lesions uncomplicated by severe hemorrhage and softening. Among the 3 patients of the unrecovered group 1 (patient 5) was severely deteriorated. The 2 others (3 and 4) were little deteriorated and should have had a fair chance of recovery. However, in case 3 uremia, nicotinic acid deficiency and a senile condition of the brain must be considered as adverse factors. In case 4 the cut was placed too posteriorly, involving the agranular frontal cortex and the caudate nucleus. In addition, extensive hemorrhage had destroyed a considerable part of the white matter of the prefrontal lobe. In case 5 the cut was placed in too anterior a plane. As regards the recovered group, it is surprising how little damage was sufficient to produce a remarkable clinical improvement. The cut in these cases was incomplete with regard to severance of the thalamofrontal fibers. From this it follows that in suitable cases (in which deterioration has not occurred) a good recovery may follow surprisingly incomplete and circumscribed cuts in the white matter of the prefrontal lobe. Recovery may be prevented by an excessive lesion, either by cutting in too posterior a plane or by causing extensive hemorrhage. The avoidance of hemorrhage seems to be a major necessity. There is some evidence that the projection of thalamic fibers to the orbital region is of considerable strength, and that the cortex in front of the surgical lesion is not wholly unaffected. The center median nucleus of the thalamus displays in the human brain a considerable variation of cell density. Its significance requires further investigation. The only conclusion that can be drawn at present is that, under both normal and psychotic conditions, the center median nucleus is liable to considerable variations in cell density and spacing of cells, which apparently far exceed those seen in animal brains. This variability is of remarkable interest if one regards the nucleus as an association center within the thalamus, which itself appears to be one of the corner stones of what one might call the anatomic substrate of personality organization. It is the more remarkable, as previous work on individual architectural differences within the cerebral cortex has demonstrated the relative constancy of the cortical pattern.

*Sickle Cell Trait in the South African Bantu. A. Altmann.—p. 457.

Sickle Cell Trait in the South African Bantu.—Sickle cell anemia and the sickle cell trait seem to be rare in South Africa. Altmann desired to confirm this fact on a larger number of specimens of Bantu blood. Of 403 blood specimens of South African Bantus only 1 showed the sickle cell trait in a moist sealed preparation after twenty-four hours' incubation at 37 C. He concludes from this that the sickle trait, which is common in West African and American Negroes, is rare in the South African Bantu.

Patent Foramen Ovale.—Vimtrup concludes that anatomically patent but functionally closed foramen ovale occurs in about 20 per cent of all adult persons and under ordinary conditions is without symptoms. If, however, the pressure in the right atrium becomes higher than that in the left, grave complications may set in; under certain circumstances even large emboli can penetrate from the right half of the heart to the left. Paradoxical emboli are not an unusual finding at necropsy; 2 cases are reported. Twenty-one cases of embolus in foramen ovale are cited.

Malignant Granulocytopenia in Chronic Rheumatic Conditions.—Edström reports that, in 1,605 cases of rheumatic fever and chronic polyarthritis from 1936 to 1940 in which gold therapy and administration of aminopyrine and salicylates were applied, 15 deaths occurred, 12 from rheumatic infection and 3 from malignant granulocytopenia, while in 819 cases from 1928 to 1933 treated mainly with salicylates and to some extent with aminopyrine there were 33 deaths, 30 due to rheumatic infection and 3 to malignant granulocytopenia. The danger of malignant granulocytopenia apparently has not been increased by the introduction of the new therapy. The complications in this antirheumatic therapy, particularly malignant granulocytopenia, are believed to be more the results of an infectious-toxic factor in an organism with strong hyperergic reaction than the results of drug reaction.

Book Notices

The Autonomic Nervous System. By Albert Kuntz, Ph.D., M.D., Professor of Micro-Anatomy in St. Louis University School of Medicine, St. Louis. Third edition. Cloth. Price, $8.50. Pp. 687, with 91 illustrations. Philadelphia: Lea & Febiger, 1945.

Eleven years have intervened since the appearance of the second edition of Kuntz's book, years containing extensive investigative work into the form and function of the autonomic nervous system and into the role of this system in diseases and the surgical approach to therapy. These advances are reviewed and interpreted in this edition, and the content of the book has materially increased without a proportionate increase in pages. This has been accomplished by increasing the wordage per page. While the chapters on the anatomy of the autonomic nervous system have retained their arrangements, much new information has been added, for example the classification of the cells of the ganglions and the cytologic data on the processes of the ganglion cells. The role of the cerebral cortex in autonomic functions, which has been considerably elucidated since the appearance of the second edition, is concisely and completely covered. There is extensive augmentation of the chapters on autonomic physiology, which is particularly true in regard to the functions of diencephalic centers. The discussion of the role of chemical mediators is elaborated to take into account the active investigations in this field, and the phenomenon of denervation sensitivity is considered in detail. Discussion of the embryologic development of the autonomic nervous system is not materially altered from that of the second edition. While the chapters dealing with the innervation of the various viscera and structures have in large part retained their original outlines, new data have been judiciously added, for example the role of the vagus in cardiospasm, the stimulability of the jejunum and the important work on the stimulation of the respiratory center by carbon dioxide. The discussion of the histopathology of the autonomic ganglion cells has been somewhat enlarged, and neuronal changes such as hydropic alterations and neurofibrillar changes are given more importance.

In considering clinical relationships Kuntz finds no brief for the theory of vagotonia and sympathicotonia. Tests for autonomic function are extensively described under the headings (1) studies of singly innervated structures as the nictitating membrane, (2) tests based on denervation of either sympathetic or parasympathetic supply, (3) assay of the output of humoral mediation and (4) the observation of pharmacologic actions. The chapter on the autonomic nervous system in disease has been enlarged to include new data such as the more recent observations on carotid sinus sensitivity, emotional factors in the etiology of peptic ulcer and the etiology of intussusception. In reviewing autonomic neurosurgery Kuntz is now able to point out that no anatomic or physiologic rationale exists for periarterial sympathectomy. The results of sympathetic ganglionectomy and ramisection are reviewed, and the effects of autonomic surgery are reviewed in the various diseases in which such surgery is performed.

No review of this book is adequate without mentioning the extensive bibliography. This edition is welcome, for it brings down to date a scholarly, well documented treatise on an important part of the nervous system. It forms a valuable addition to the library of all concerned with neurology and it can be recommended without reservation.

Aviation Neuro-Psychiatry. By R. N. Ironside, M.B., F.R.C.P., Neurologist, West London Hospital, London, and I. R. C. Batchelor, M.B. Cloth. Price, $3. Pp. 167. Baltimore: William Wood & Company, 1945.

This book is a record of the authors' experiences overseas with Royal Air Forces combat units. It contains details concerning neurologic and psychiatric disabilities. The contents are a dull, nondynamic recapitulation of case histories of disabled fliers of the type found in any textbook. The drama, pathos and heroics of active combat are absent, as are the dynamic factors in the production of the war neuroses. Treatment consists for the most part in permanently grounding. American flight surgeons who were not specialists were far ahead of these neuropsychiatrists in their knowledge and therapeutic ability.

Industrial Oil and Fat Products. By Alton E. Bailey, Senior Chemical Technologist, Southern Regional Research Laboratory, U. S. Department of Agriculture, New Orleans, Louisiana. Cloth. Price, $10. Pp. 735, with 111 illustrations. New York: Interscience Publishers, Inc., 1945.

This book has been prepared by an author well versed in the technical aspects of fat and oil processing and their commercial applications. The benefit of advice from numerous experts in the various fields has been utilized, as is so desirable in literature presenting the complex problems of modern industry. The work may be considered as a textbook directed to industrial technologists. It covers briefly the chemical characteristics and nutritional properties of fats in its opening section as a background for the reader. Subsequently the material is developed in discussions on the sources of all known types of fat compounds, including production and consumption figures. The uses to which the various oils are placed in food production and other manufactured products, with the factors determining the selection of each for specific purposes, comprises a section of the book which is particularly well done. The final portion deals with physical and chemical processes to which fats and oils are commonly subjected in their preparation for various uses, from the original extraction by pressure or by solvent to treatment by chemicals for purification, fractionation or other special effect. The material is clearly presented in a well organized manner. It is documented freely by references to the original work from which the facts were obtained. The numerous tables and diagrams add much to the information supplied. The predominance of references are of very recent years. The book would appear to be an indispensable volume in any library of technical information on fats.

Sechenov. Akademiya Nauk Soyuza SSR, nauchno-populyarnaya seriya, biografii. [By] Kh. S. Koshtoyants. [Sechenov. Academy of sciences of U.S.S.R., Scientific Popular Series, Biography.] Cloth. Pp. 199, with portrait. Moscow & Leningrad: Izdatelstvo Akademii Nauk SSSR, 1945.

This interesting biography in Russian deals with the man who is referred to by the Russians as the father of Russian physiology. While the name of Pavlov is well known in this country, not only among scientific circles but even among laymen, that of Sechenov is probably known only to workers in his particular field. Born in 1829, Sechenov belongs to that small but elite group of scientists who are the true glory of Russia's science. This group includes such names as Mendeleev, A. P. Borodin, A. N. Beketov, A. O. Kovalevskiy, V. O. Kovalevskiy and Mechnikov. As did most ambitious Russian students of that age, on his graduation from the University of Moscow, Sechenov spent several years abroad. Here he had the privilege to work under such men as Du Bois Reymond, Carl Ludwig and Helmholz and to listen to the lectures of Johannes Mueller. While working in the laboratory of Claude Bernard, Sechenov made the important observation that there existed in the brain of a frog special mechanisms capable of inhibiting reflexes proceeding from the spinal cord. This was a discovery of a special physiologic function of the brain. His researches were published in 1863 under the title "Reflexes of the Brain." Somewhat later he published "Physiology of the Nervous System," in which he developed the hypothesis that all conscious and subconscious acts are in their essence reflexes. This was a startling idea for the time, namely that all psychic life with all its manifold manifestations is activated and maintained by stimuli which the organism receives from outside as well as with stimuli originating within the organism. Sechenov argued that loss of sensory stimuli or loss of sensations would render psychic life impossible. The principal cause of every act of a human being is to be found outside of him, in his environment. He arrived at a further conclusion that sensory stimuli need not necessarily be manifested by a motor act or any other external manifestation because the organism possesses nervous centers capable of inhibiting reflexes. This conclusion finds basis in his discovery that in the brain of a frog there exist special nervous centers which, when stimulated, will inhibit the development of reflex activities. This capacity for the elaboration of special reflex controls by retardation or inhibition of external manifestation of the reflex mechanism Sechenov considers the most important acquisition by man, constituting in fact the basis of that complicated process which is referred to as thought, intention, desire. Thought, according to Sechenov, is a reflex in its conception and its continuation but without the terminal act which is expressed in motion. The researches of Sechenov laid the foundation for the work of the Pavlov school. Pavlov himself stated that Sechenov's "Reflexes of the Brain" constituted the starting point of the researches of his own school. The essential similarity and kinship in the work of Sechenov and of Pavlov is that for both the formulation of the most complex acts of the so-called psychic activity depends on the environment. The study of conditional reflexes has demonstrated that the manifold manifestations of the higher nervous activity are the result of constant correlation between the organism and its environment. Both men stressed the objective physiologic method in the investigation of complicated psychic phenomena.

Analyze Yourself: Enabling Anyone to Become Deeply Psycho-Analyzed Without a Personal Analyst. By E. Pickworth Farrow, M.A., D.Sc. With a foreword by the late Professor Sigmund Freud, M.D., LL.D. Second edition. Cloth. Price, $2. Pp. 157. New York: International Universities Press, Inc., 1945.

Because of neurotic difficulties the author, a nonmedical professional man, underwent two trials of psychoanalysis with poor results. Each analyst seemed to offend the author, although he felt some improvement from the analytic experiences. He then continued his analytic procedure by having daily hourly appointments with himself, using written free associations. By so doing he dissolved certain repressions and uncovered crucial infantile memories with subsequent therapeutic benefits. The author therefore recommends the process of self analysis and describes its technics in detail. Certain personal discoveries made on himself are used to illustrate the process. Included is a dissertation on the disastrous effects of slaps and blows on infantile omnipotence when administered sufficiently hard to cause pain to the small child.

As Freud states in his foreword, the author uses a technic which was expounded in "The Interpretation of Dreams," although the results are in no way similar. This little book is fascinating and most convincing as to the capacity within some individuals for a type of self analysis. It also reveals a great deal about the author and indicates why he could profit by this procedure as contrasted with the majority of people.

The Adjustment of the Nervous Veteran in Industry. By Meyer Brown, M.D., Ph.D. Paper. Pp. 52, with 4 illustrations. Chicago: Zurich Insurance Companies, Industrial Welfare Department, [n. d.].

Among the many articles and books written for the psychiatric edification of the lay person this brochure is one of the best. Written by a competent psychiatrist who has had long practical experience in the Navy, the problems of the interpersonal adjustments of management and veteran labor are discussed in simple, easily understood language. Direct and specific sound advice is given. This is a book that should be widely recommended to industrialists and business men who wish to help service veterans who have become nervous.

Manual of Psychological Medicine for Practitioners and Students. By A. F. Tredgold, M.D., F.R.C.P., F.R.S.E. Second edition. Cloth. Price, $5. Pp. 308. Baltimore: William Wood & Company, 1945.

This work continues to be a dull and dry textbook of psychiatry which could hardly satisfy the needs of the practitioner or stimulate the interest of students. Two thirds of the book is devoted to organic disease of the brain, the psychoses, mental defects and legal problems which are not the areas of psychiatry that most concern the nonspecialist. The section on treatment is insufficient for any one to grasp the essentials. The dynamic states of the human mind cannot be grasped by perusal of this book.

Best Sports Stories of 1944. By I. T. Marsh and Edward Ehre. Price, $3. Pp. 335. New York: E. P. Dutton & Co., Inc., 1945.

Often the best action writing is that which comes hot off the typewriter in the very midst of some contest in the field of sport. Superiority in sport means also the development of colorful personalities who reflect themselves in interviews and in autobiographical statements. The very best of this writing is assembled in the collection of best stories made by Irving T. Marsh and Edward Ehre. About as fine a philosophical contribution as has appeared in many years and one especially reflecting humanity is the interview with Sam Langford, which heads the list.

Elements of Foods and Nutrition. By Mary T. Dowd and Alberta Dent. Second edition. Fabrikoid. Price, $2.25. Pp. 357, with 37 illustrations. New York: John Wiley & Sons, Inc.; London: Chapman & Hall, Limited, 1945.

This is intended as a primer which will arouse the young or uninitiated reader to the importance of good nutrition for good health. The earlier edition, published in 1937, has been completely revised to incorporate the basic nutritional advances made since then. The space devoted to actual discussion of the facts of nutrition is rather limited, whereas more attention is given to a description of the classes of foods and their contribution to a good diet and the proper preparation and use of these foods. Attention is directed to the needs of the family group as well as the individual. Recommended menu patterns are provided, and a feature not found in other books is a critical appraisal of the strength and weakness of racial dietary habits. A discussion of food fads and fallacies lends an interesting conclusion. The style of the book is highly simplified. In some cases rather loose statements are made, the accuracy of which might be questioned. The inclusion of questions and references after each chapter is a fine stimulus for the reader and of help to the teacher. The volume is well suited for use as a textbook in teaching nutrition through the high school level.

The Effect of Bombing on Health and Medical Care in Germany. Morale Division, United States Strategic Bombing Survey. Medical Branch Report. Fabrikoid. Pp. 388, with 196 illustrations. Washington, D. C.: War Department, 1945.

The effect of bombing from the air on the health and well-being of the residents of a modern industrial state like Germany inevitably must be profound. This book corroborates that belief. In it an effort has been made to document scientifically the number of deaths from bombing in Germany, the effect of bombing on communicable diseases, the destructive effect of bombing on medical schools, hospitals and sanitary installations, and the influence of bombing alone on the food supply and nutrition and supply of drugs and other medical equipment. Some of the information which is contained in the book has been the subject of newspaper articles, news from Germany in the foreign letters department of THE JOURNAL, correspondence and special articles. This book, nevertheless, presents an all-over picture of the effect of air raids which confirms the generally held belief that bombing alone profoundly influences the lives and health of all those in any large or concentrated population.

Oral Health. By H. Shirley Dwyer, D.D.S., Director, Division of Dental Services, New Hampshire State Department of Health, Concord. Cloth. Price, $1.25. Pp. 132, with 12 illustrations. Philadelphia & London: W. B. Saunders Company, 1945.

This book is planned particularly for health workers. It gives, in brief, information regarding the growth and development of the teeth and the causes of dental decay, the facts regarding prevention and prophylaxis in dentistry and much about the care of the more common diseases of the mouth. Other chapters concern the place of the public health nurse in a dental program and the meaning of health education. A final chapter deals with questions that a nurse is frequently asked and the answers to such questions.

A Companion to Manuals of Practical Anatomy. By E. B. Jamieson, M.D., Senior Demonstrator and Lecturer on Anatomy, University of Edinburgh, Edinburgh. Sixth edition. Fabrikoid. Price, $4.50. Pp. 736. New York, Toronto & London: Oxford University Press, 1945.

This book was originally written to provide an accurate account of gross anatomy in a small, compact and readily accessible form. That the book has attained this goal is attested by the appearance of the sixth edition. It has been written largely from the regional approach rather than the systematic. This is an advantage for those desiring to carry out various dissections. The only criticism against the book is that the Birmingham Revision of nomenclature has been adopted throughout the text. As to whether or not this is a disadvantage depends on the point of view of the individual anatomist or physician using the book. Many American anatomists strongly urge the retention of the BNA system of terminology until modifications are officially adopted by the various anatomic associations. They also believe that the use of any other system of terminology in the meantime would be detrimental to the best interests of science.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

VACCINES FOR DYSENTERY

To the Editor:—What is the present status of dysentery vaccine as a prophylactic measure? I understand that it is recommended in institutional or other outbreaks of dysentery but that the period of immunization is relatively short. Would there be any practical basis for routinely giving each new admission to a state hospital a prophylactic course of dysentery vaccine in the absence of an epidemic or of any known cases of the disease?

M.D., Pennsylvania.

ANSWER.—Extensive studies of dysentery vaccines have been conducted in the past two years under the sponsorship of the Committee on Medical Research of the Office of Scientific Research and Development. During these investigations the vaccines were used extensively in institutions in which dysentery was endemic or epidemic. The results were disappointing. The total numbers of individuals, cases and carriers, who acquired infection in the vaccinated and control groups were essentially the same. In one institution 265 patients were vaccinated and 264 observed as controls. Among these there were 45 and 48 clinical cases respectively and 127 and 128 identified passive carriers respectively. The vaccines which appeared most promising were used in these tests. It is concluded, therefore, that dysentery (Shigella) vaccines as prepared and given at present have no practical value in the control of these infections.

SYMPTOMS IN POISONING WITH METHYL ALCOHOL AND ETHYLENE GLYCOL

To the Editor:—What are the physical observations in methyl alcohol poisoning? Would the ingestion of either methyl alcohol or Prestone (ethylene glycol) by a man aged 40 produce methemoglobin of 30 volumes per cent, coma of about twelve hours' duration, Kussmaul breathing, blood pressure of 110/40-0 with complete anuria of about the same duration, normal spinal fluid, with bilateral internal strabismus, normal fundi ophthalmoscopically, a terminal white blood cell count of 60,000, all superficial reflexes absent and negative Babinski and recti? Four hours following administration of 2,000 cc. of 5 per cent glucose in an isotonic solution, knee and Achilles reflexes reappeared, and blood pressure rose to 180/90. Examination four hours later revealed that these reflexes were again absent and the blood pressure was 110/40-0. Death followed six hours later. About 1 ounce of urine was obtained at the first examination sixteen hours before death; this showed normal sugar and albumin and many pus cells. Would any treatment other than intravenous fluids, oxygen with 5 per cent carbon dioxide and supportive treatment have been indicated?

Clifford W. Atherton, M.D., Stambaugh, Mich.

ANSWER.—The symptoms and physical signs of methyl alcohol poisoning as it occurred among a large number of Navy personnel have recently been described by Jacobson, Russell, Grimm and Fox (*U. S. Nav. M. Bull.* **44:**1099 [May] 1945). The symptoms include mild alcoholic intoxication, headache, supraorbital or retro-orbital pain, blurred vision, loss of color vision, first for green, then for red and yellow and finally for blue, central scotoma, abdominal cramps, nausea and vomiting, drowsiness, loss of memory, confusion and coma. An odor of methyl alcohol may be detected on the breath. The physical signs are a flushed face or cyanosis of the chest, face and fingertips, slight fever with proportionately rapid pulse and dilated pupils that react sluggishly or not at all to light. When coma supervenes, the dilated pupils are usually fixed; the skin is cold, moist and clammy; the respiration is labored and deep (5 per minute) and the pulse rapid and thready. In 1 case, however, the pulse was full, bounding and slow (40 per minute) and continued so for ten minutes after respiration had ceased. In many but not all of the fatal cases death was preceded by a series of convulsive seizures described as being of the decerebrate type. Aside from these and the fixed pupils no neurologic abnormalities were described. Examination of the fundus showed mild hyperemia of the disk and retina, haziness of the disk margins and slight engorgement of the blood vessels, most noticeable in the macular area. The urine was acid (p_H 5.5, 6.0) and usually contained traces of albumin and numerous hyaline and granular casts. Methyl alcohol was readily found in the blood.

Cases of poisoning by Prestone (ethylene glycol) have been few in number and inadequately described (THE JOURNAL, June 14, 1930, p. 1940).

In the case described in the query, the meaning of the statement "methemoglobin of 30 volumes per cent" is not clear. If it is meant that 30 per cent of the blood pigment had been converted to methemoglobin, the observation would suggest an intoxication. Methemoglobin formation is not, however, a feature of intoxication by methyl alcohol, nor has it been found in animal experimentation with the glycols. An overdose of such a drug as acetanilid or sulfonal might conceivably give rise to this clinical picture. It could also occur as the result of poisoning by nitrobenzene, aniline or some related compound, although in the case of nitrobenzene poisoning the urine is usually dark. The other features of the case, with the exception of the leukocytosis, are compatible with fatal intoxication induced by alcohols and a number of other organic solvents. The origin of the leukocytosis is not apparent and may be irrelevant. As to therapy, if a state of acidosis was present it could have been corrected by the intravenous administration of a solution of sodium bicarbonate. Its presence could have been determined by measuring the alkali reserve in the blood or, if facilities for this were lacking, by measuring the p_H of the urine. This procedure has been found effective in such cases.

AMPHETAMINE AND THYROID FOR OBESITY DURING PREGNANCY

To the Editor:—I have been treating a young woman successfully for obesity with tablets containing thyroid and amphetamine. She has now become pregnant. Are there any contraindications to the continuance of this medication because of her pregnancy? Are there any reasons to expect any harm to the fetus?

M.D., New York.

ANSWER.—In general it is unwise to give amphetamine (benzedrine sulfate) during pregnancy. It would not be very good treatment even if the woman was not pregnant. It was originally recommended in weight reduction because it was supposed to reduce the appetite for food. It is of doubtful value for this purpose. Moderate doses of thyroid would probably not harm either the mother or the fetus during pregnancy, but the condition of the mother should be checked carefully while she is receiving it. A rigid weight reducing diet should not be continued after a patient becomes pregnant. Both mother and fetus require a well balanced diet that is adequate in all respects. In obese women some restriction of the total caloric intake may be desirable during pregnancy in order to prevent gain in weight, but it is doubtful that weight reduction should be carried out during pregnancy.

SULFOBROMOPHTHALEIN TEST

To the Editor:—I would appreciate knowing what amount of dye was used by Colonel Barker and his associates in their sulfobromophthalein test (The Journal, Nov. 3, 1945, p. 653). Some use 2 mg. per kilogram and others 5 mg. per kilogram.

Albert F. Brown, M.D., Glendale 6, Calif.

ANSWER.—Sulfobromophthalein 5 mg. per kilogram of body weight was used in all cases studied in the Mediterranean theater (THE JOURNAL, Aug. 4, 1945, p. 997, and Nov. 3, 1945, p. 653). Bloods were drawn at one-half hour and one hour in approximately one half the cases, while the remainder had samples taken at forty-five minutes and one hour. Control studies in soldiers in 1942-1945 indicated that the technic of using 5 mg. per kilogram with samples drawn at forty-five minutes were generally most satisfactory. If 2 or more per cent of dye is retained at the end of forty-five minutes, a second sample was drawn at the hour. Any retention at the hour or failure to reduce further the forty-five minute level was generally abnormal except in the convalescent period from certain acute infectious diseases.

INJECTION OF PROCAINE FOR FOOTBALL INJURIES

To the Editor:—Is it considered good practice, in the treatment of football injuries in which fracture is not present, to inject a knee or ankle with procaine? If so, what is the technic? Is it advisable to let a player continue playing following such an injection?

D. L. Hollis, M.D., Biloxi, Miss.

ANSWER.—It is good practice to inject a sprained ankle with procaine when a fracture has been proved absent by x-ray. This does not hold for knee injuries. This injection treatment could be used in football injuries but immediate resumption of play should not be allowed, nor can a cure be expected in every case. One method is to inject, under sterile precautions, 2 to 5 cc. of a 2 per cent solution of procaine into the tender spot on the ligament. Care should be taken not to inject into a blood vessel. It is well to aspirate first and, if no blood is withdrawn, to inject the procaine without withdrawing the needle. Immediate motion should be started. If the next day no pain recurs, it would be allowable to indulge in football. Even so, the ankle should be well strapped with adhesive tape to prevent recurrence of the sprain.

ACTION OF PENICILLIN, ESPECIALLY ON TREPONEMA PALLIDUM

CHESTER N. FRAZIER, M.D.
and
EDWARD H. FRIEDEN, Ph.D.
Galveston, Texas

The precise way in which penicillin acts to destroy microbial life is unknown. Penicillin differs, however, from the common antiseptics, such as the phenols, in that it is not a general protoplasmic poison. In this respect it resembles other antibiotic substances as well as the sulfonamides, which act primarily by inhibiting the growth of the cell. For this reason it is generally assumed that penicillin interferes with the normal completion of some metabolic transformation, thus inhibiting the development of the cell and leading eventually to its death.

Certain antibacterial substances are inhibited by specific chemical agents. The identification of the inhibitor has contributed in some instances to a clearer understanding of the essential mode of action of the antibacterial substance, as for example the inhibition of the sulfonamides by para-aminobenzoic acid. In this instance the phenomenon has been explained by the fact that para-aminobenzoic acid is a factor in bacterial nutrition closely related in chemical structure to the sulfonamides in that the sulfonamido group of the latter is replaced by a carboxyl group in the para-aminobenzoic acid molecule. It is thought, therefore, that at some vital stage of bacterial metabolism there is competition between the sulfonamide and para-aminobenzoic acid for an enzyme, with the result that the sulfonamide, not possessing the specific action of the metabolite, interrupts the normal metabolic process with which the substrate is concerned. This is an engaging hypothesis, although there may yet be no direct proof to support it.[1]

A similar example of competitive inhibition is had in the action of pantoyltaurine on the growth of hemolytic streptococci and Corynebacterium diphtheriae.[2] Inhibition of growth in this instance is the result apparently of an interference by pantoyltaurine with the utilization of pantothenic acid by the bacterial organisms.

ANTIBACTERIAL ACTION OF PENICILLIN

Potency.—Penicillin is the most potent, and yet nontoxic, antibacterial substance yet applied to the treatment of clinical disease. The purest penicillin thus far available inhibits the growth of the most sensitive organisms, such as the staphylococcus and gonococcus, in dilutions of about 1 : 50,000,000. Preparations now in clinical use will inhibit at dilutions of from 1 : 5,000,000 to 1 : 15,000,000 under optimal conditions.[3] As little as 0.04 unit per cubic centimeter of penicillin (corresponding to about 0.02 microgram of the pure substance) is sufficient to kill 200 million organisms. This activity is of the same order as that of the highly active enzymes and suggests that penicillin is a part of an enzyme or actuates an enzymatic system.[4]

The preparations of penicillin in general use are mixtures of the sodium salt and different amounts of other substances of an unknown nature. Apparently, it is some fraction of partially purified penicillin which is effective in the treatment of syphilis. This possibility is suggested by the observations of Dunham and Rake,[5] who found that crystalline penicillin G did not immobilize Treponema pallidum in the same concentrations as did the partially purified penicillin. A substance in the latter which can be concentrated by adsorption on alumina possessed the greatest antispirochetal action.

Although crystalline penicillin G did not immobilize spirochetes in vitro, it did possess in large doses some degree of antisyphilitic action, as shown by its ability to modify the reaction of the rabbit to infection with Treponema pallidum.

The effect of purification on the antispirochetal potency of penicillin is evident in the results of immobilization tests and in the protection afforded laboratory animals against syphilitic infection. The alumina adsorbate immobilized all spirochetes in concentrations equivalent to 2,200 units per cubic centimeter, but 8,800 units per cubic centimeter of a recently prepared commercial penicillin failed to immobilize all organisms. Crystalline penicillin G in a dilution of 8,800 units per cubic centimeter had no effect on motility. Partially purified penicillin (330 units per milligram) protected 4 out of 5 rabbits from infection as determined by lymph node transfers when 66,000 units per kilogram of body weight was injected intramuscularly five hours after a suspension of Treponema pallidum was rubbed into an incision of the skin. The same dose of crystalline penicillin G failed to protect animals under similar conditions.

Further evidence that the antispirochetal potency of penicillin resides in one or more of the impurities in the preparations was had in the failure of weak solutions of penicillinase to reduce the immobilizing activity of the substance under conditions which would inactivate a large part of the penicillin present.

Selective Action of Penicillin.—In general, the gram-positive organisms are sensitive to penicillin, as also are the gram-negative cocci, but the gram-negative bacilli are insensitive. Some species, however, show strain variations. Penicillin has in vitro a high degree of specificity for the pyogenic cocci, pneumococci, anaerobic clostridia and the pathogenic gram-negative cocci Neisseria gonorrheae and Neisseria meningitidis. There is, however, a lack of sensitivity on the part of the colon-typhoid group and the hemophilic and chromogenic bacilli. The tubercle bacillus and Trypanosoma equiperdum are resistant,[6] but both Treponema pallidum and Borrelia novyi are inhibited by its action, as apparently are also Leptospira icterohemorrhagiae and Spirillum minus.[7] Recent clinical observations indicate that the spirochete of yaws is also sensitive to penicillin,[8] and favorable results have followed its use in fusospirochetosis.[9]

Treponema Pallidum.—In December 1943 Mahoney, Arnold and Harris [10] reported the beneficial effect of penicillin on 4 patients with seropositive primary syphilis. A short time thereafter Dunham, Hamre, McKee and Rake [11] found that relatively high concentrations of penicillin, from 800 to 1,600 units per 0.8 cc., affected in vitro the motility of Treponema pallidum. The organisms were obtained from the testes of experimentally infected rabbits in the stage of acute orchitis. It was shown also by Eagle and Musselman [12] that penicillin exerted a spirocheticidal effect on artificially cultivated strains of spirochetes.

The immediate effects of penicillin on early syphilitic infections in man have been satisfactorily demonstrated by the disappearance of surface organisms from open lesions, the healing of lesions and a trend toward the reversal of serologic reactions.[13]

Attempts have been made to establish the minimal healing and sterilizing doses of penicillin in experimental syphilis of the rabbit, but the results thus far have lacked definitive significance.[14] In general, single large doses have not proved effective as far as permanent suppression of the infection is concerned. It is becoming increasingly clear that the proper spacing of adequate doses of penicillin over a period of time, yet undetermined from the human subject, will be required for the permanent control of the infection, if that can be achieved.

Single intravenous doses of from 33,000 to 47,000 units per kilogram were required to produce disappearance of spirochetes from scrotal chancres in the rabbit. The same effect was obtained with about 16,000 units per kilogram when the drug was administered in repeated doses of approximately 4,000 units per kilogram over a period of seventy-two hours. The latter dose was sufficient to produce healing of the testicular lesions in from ten to fifteen days. Lymph nodes of 4 rabbits treated with 132,000 to 282,000 units per kilogram were proved subsequently to be infectious. Selbie and Simon [15] found that 45,000 units per kilogram, when given to rabbits in three equally divided doses at intervals of three hours, caused the disappearance of organisms within twenty-four hours as determined by the direct examination of testicular lesions. Organisms, however, reappeared in the majority of the lesions in from thirty to forty-five days after treatment. In these experiments it is apparent that the factor of time as related to dosage was at fault.

MECHANISM OF ACTION

There is a body of facts relating to the biologic conditions which limit, or proceed from, the effects of penicillin that help to define the mechanism of its action. These have been adduced chiefly from in vitro experiments with the more sensitive micro-organisms such as the pyogenic cocci, the pneumococcus and the gonococcus. Only a few similar observations have been made on the behavior of Treponema pallidum. The lack of suitable biologic materials and technics for the study in vitro of this most fastidious organism has imposed limitations on laboratory investigation.

Antibacterial Action.—It is becoming more apparent that penicillin acts chiefly as a bactericidal agent. According to a recent statement of Chain and Duthie [4] there is no conclusive evidence that it can exert a purely bacteriostatic effect under any condition.

The bactericidal action of penicillin, originally suspected by Fleming,[16] was doubted at first by Abraham and Chain,[17] who were unable to detect any disturbance in oxygen uptake of resting staphylococci even in high concentrations of the antibiotic substance. Hobby and her associates,[18] however, observed a powerful killing effect of penicillin on pneumococci, hemolytic streptococci and staphylococci under conditions permitting rapid baterial growth. The number of surviving organisms decreased geometrically as the time of action increased by arithmetical units until at least 99 per cent of the organisms were killed. Bactericidal action was enhanced by substances favorable to bacterial growth and diminished by those interfering with growth.[19] A similar mode of action on the meningococcus was observed by

Miller and Foster;[20] and Rammelkamp and Keefer[21] found evidence of bactericidal action on the streptococcus and staphylococcus in human blood.

The rate of killing is characteristic of the organism and varies inversely with the original number of organisms in the culture and directly with the concentration of penicillin up to certain limits, beyond which increases in concentration apparently no longer enhance its effectiveness. No appreciable amount of penicillin is absorbed or destroyed as a result of antibacterial action. Perhaps most significant of all is the finding that the greatest destruction of organisms occurs during the phase of rapid multiplication.

Recently Chain and Duthie[4] reported that during the resting phase of the cultural cycle of the staphylococcus large concentrations of penicillin had no effect on the rate of oxygen uptake. However, during the early lag phase and the logarithmic phase of growth, penicillin in very small concentrations (0.04-0.1 unit per cubic centimeter) exerted a strong inhibitory effect on oxygen uptake and eventually stopped the process altogether. This would confirm the earlier observations and indicates that penicillin kills bacteria in the phase of multiplication but does not kill them in the resting stage. It would appear, therefore, that penicillin interferes with a metabolic function involved in the early stages of bacterial development.

In this respect there is evidence that the sulfonamides act in a manner similar to penicillin, with the exception that penicillin is capable of destroying bacteria in the early lag phase of growth before actual cell division begins, whereas the sulfonamides exert a similar action only after a number of cell divisions have occurred in its presence.[22] As pointed out by Chain and Duthie, it is probable that conditions occur in the body under which micro-organisms may be in the resting stage and thus be insusceptible to the action of penicillin.

The fact that penicillin as well as some of the other antibiotics (gliotoxin, aspergillic acid, bromoaspergillic acid and fumigacin)[11] are the only chemotherapeutic agents besides the arsenical, bismuth and mercurial compounds which are effective against Treponema pallidum suggests that a careful consideration of the mechanism of action of the latter may be helpful in interpreting the available data relating to the mechanism of the action of penicillin.

THE MECHANISM OF SPIROCHETICIDAL ACTION OF THE ARSENICAL COMPOUNDS

It was once generally accepted that the arsphenamines had no direct spirocheticidal action and that their effectiveness depended on the conversion of the arsenical compound in the body into some other substance or on the stimulation of some obscure mechanism of defense in the body. Doubting these assumptions, Eagle[23] in a series of experiments found no evidence to support the view that the arsphenamines are themselves inactive or are converted by the tissues to a spirocheticidal agent. In fact, he observed that tissues such as testicular extractives inhibited rather than accentuated the antispirochetal action of the arsenical. He was able to show further that the trivalent arsenicals and a phenylarsenoxide[23] had a definite spirocheticidal effect in vitro in dilutions as high as those attained in vivo after therapeutic administration of these drugs.

Several years ago, in a study of the trypanocidal action of arsenical drugs, Voegtlin, Dyer and Leonard[24] suggested that arsenic may combine with the sulfhydryl groups in the organism in the process of its destruction. They observed that cysteine significantly retarded or abolished in vivo the trypanocidal action of the arsenical, presumably because the excess cysteine competed for the arsenical with a sulfhydryl component of the trypanosome.

Later, in testing this hypothesis, Eagle[25] found that various sulfhydryl compounds (cysteine, glutathione and thioglycolic acid) almost completely abolished the antispirochetal action of arsenical, mercurial and bismuth compounds in vitro in what was probably a freely reversible reaction. The fact that all the antispirochetal agents tested were rapidly and almost completely inactivated by the addition of sulfhydryl compounds suggested to him that they may owe their therapeutic activity to similar combinations with sulfhydryl groups in the spirochetes.

In this connection it should be emphasized, as pointed out by Eagle, that the action of sulfhydryl compounds in inhibiting the spirocheticidal and trypanocidal action of the arsenoxides is insufficient to prove that the therapeutic action of these compounds is effected by combination with labile sulfhydryl groups within the sensitive organism. It is possible that the action of the inhibitor is merely to block the arsenic-containing molecule so that the latter is unable to affect a reaction completely unrelated to — SH metabolism. However, the fact that such inhibitors are equally effective against the arsphenamines is powerful support for this attractive hypothesis. There is no a priori reason to suppose that the reaction between sulfhydryl compounds and arsphenamine or related compounds proceeds to any considerable extent, at least in vitro. There is ample evidence that the arsphenamines do not require conversion into arsenoxides in order to exert their spirocheticidal and trypanocidal effects.[26] The inhibitory effect of various sulfhydryl compounds in this case, therefore, suggests an intimate relationship between such compounds and the physiologic process, or processes, affected by the drug.

MECHANISM OF ANTISPIROCHETAL ACTION OF PENICILLIN

Action in Vitro.—Pathogenic strains of Treponema pallidum have not been cultivated on artificial mediums. However, strains which purport to be Treponema pallidum have been cultivated. These are not pathogenic for animals and differ morphologically from the true organism. The so-called Reiter's strain grows luxuriantly in Brewer's thioglycolate medium, enriched with one-tenth volume of heated rabbit's serum.

Using the Reiter strain of spirochete, Eagle and Musselman[12] found that penicillin in threshold concentrations of 0.01 unit per cubic centimeter was actively spirocheticidal in vitro and that the rate and degree of action increased with the concentration of penicillin up to a level of approximately 0.1 to 0.25 unit per cubic centimeter. At this level fully 99 per cent of the organisms were made nonviable within twelve hours, as indicated by their failure to grow in subcultures. This effect was not improved by higher concentrations of the antibiotic agent.

Organisms remained actively motile for a period of from eight to twenty-four hours after they had become nonviable from contact with the penicillin. As doses of penicillin approximately 10,000 times those required to inhibit the growth of the spirochetes in subcultures did not accelerate the immobilization of the organisms, it was the impression that the metabolic system affected was not immediately essential to the life of the spirochete.

It was also demonstrated that the rate at which organisms were killed increased with temperature in the range of 8 to 40 C., the increase being independent of the concentration of penicillin employed (0.25 to 250 units per cubic centimeter).

Action in Vivo.—Suspensions of pathogenic Treponema pallidum obtained from testicular lesions of the rabbit were not immobilized in from two to six hours by concentrations of penicillin up to 500 units per cubic centimeter. Since the motility of the highly susceptible cultured spirochetes was not affected in that period of time and in those concentrations, it was thought that the observation did not exclude a direct spirocheticidal effect. In the case of the cultured organisms, penicillin was actively spirocheticidal in minute doses yet did not affect the motility of the organism. In other words, it seems probable that penicillin may directly inhibit the function of multiplication of the spirochete without initially destroying its power of motion.

When partially purified penicillin in concentrations insufficient to cause complete immobilization of pathogenic strains of Treponema pallidum were used, Dunham and Rake [5] saw that the last form of motion to be lost was the bending of the body of the spirochete near the midpoint. This suggested to them that axial rotation of the organism is caused by the motion of its flagella. In such case the flagella would appear to be more sensitive to penicillin than is the body of the organism.

These investigators also found that penicillin probably destroys the reproductive capacity of the spirochete without inhibiting its function of locomotion. Spirochetes exposed to 1,100 units per cubic centimeter of partially purified penicillin did not produce demonstrable signs of disease in rabbits over a period of two months, although many spirochetes were still motile at the time of inoculation. Mixtures containing 550 units per cubic centimeter and those containing 1,100 units per cubic centimeter showed little difference in the percentage of motile organisms, but the difference in the infectivity of the two mixtures was extreme.

It will be recalled that Eagle and Musselman observed a similar differentiation of action on cultivated strains of spirochetes. The results of the in vivo experiments of Dunham and Rake were inconclusive, however, since the possibility of latent infection in the rabbits was not excluded.

As the rate at which spirochetes were killed by penicillin was independent within wide limits of its concentration, it was suggested that, if an effective level of penicillin could be maintained in the tissues, further increase in the size of individual doses would add little to the efficacy of treatment.

This suggestion accords with the facts as they are known concerning other micro-organisms sensitive to the action of penicillin. Increasing the minimal concentration of penicillin which will completely inhibit an inoculum of certain strains of bacteria in a stated period of time does not alter the rate or the extent of bacterial inhibition per unit of time.

As pointed out by McDermott, Benoit and Dubois,[27] once the minimal effective concentration of penicillin is attained, remission of syphilitic disease will occur, and much larger concentrations of the antibiotic agent per unit of time serve no useful purpose; only by the maintenance of the minimal effective level for a period much longer than that which establishes the primary remission can a relapse of the disease be prevented. There is also reason to believe that the maintenance of effective levels of penicillin in the tissues for a prolonged period of time need not be continuous. The absolute values of the minimal effective level of penicillin and the time over which it must be maintained obviously must vary with the micro-organism and probably with the nature of the tissue reaction which it produces. The factor of tissue reaction would seem to be of importance in a disease such as syphilis, in which the reaction in the early acute phase differs measurably from that of the late chronic phase, especially as it involves the central nervous and cardiovascular systems.

The minimal concentration of penicillin which will completely inhibit Treponema pallidum in vitro is not known. Certain streptococci and other organisms are inhibited by concentrations ranging from 0.01 to 0.02 unit per cubic centimeter. The Reiter's strain of spirochete can be inhibited completely in vitro for a period of seven days by concentrations of from 0.02 to 0.05 unit per cubic centimeter.[12] Concentrations of penicillin of 0.01 to 0.04 unit per cubic centimeter in the blood serum are associated with rapid disappearance of spirochetes from the surface lesions and healing of the lesions. On the basis of such information it has been assumed by McDermott that a concentration of penicillin in the serum of 0.078 unit per cubic centimeter is probably well above the minimal effective level for the destruction of the spirochete. (This is the lowest concentration of penicillin which can be measured in serum by the Rammelkamp method.) It would appear that blood levels of this height are maintained for a period of ninety minutes following a single intramuscular injection of 20,000 units of penicillin and for one hundred and twenty minutes following an injection of 40,000 units.[27]

It should be remembered, however, that concentrations of penicillin in the tissues may not be at the same level as in the serum, particularly in relatively avascular regions, so that a much higher serum level might be necessary to maintain an effective spirocheticidal concentration in such tissues.

The length of time during which effective levels must be maintained, and whether such levels need be continuous or might better be intermittent, are problems which have not yet been solved either in the laboratory or in the clinic.

EFFECT OF PENICILLIN ON MORPHOLOGY OF MICRO-ORGANISMS

It has long been known that the form of a bacterial cell is affected by the presence of other micro-organisms or by substances they produce. Borodulina[28] observed that antibiotic substances produced by actinomycetes influenced the growth of Bacillus mycoides in such a way as to delay cell division. As a result, the organisms became elongated and grew to an enormous size, often exhibiting a bizarre pleomorphism.

Gardner[29] saw that cultures of Clostridium welchi, when growing in the presence of penicillin at concentrations less than those required for complete inhibition of growth, developed an extreme elongation of the majority of cells. These took the form of segmented filaments often ten or more times as long as the normal cell. By further investigation this phenomenon was found to be characteristic of all bacillary forms which displayed any inhibition of growth in the presence of penicillin. On exposure to incompletely inhibitory concentrations, pleomorphism is also developed by other organisms, among them staphylococci, streptococci and the cholera vibrio. It was thought that the changes in form are due chiefly to the continuation of growth without the usual division and separation of cells.

Similar morphologic changes in the gonococcus in smears from patients under treatment with penicillin were described by Miller and his co-workers.[30] Alterations in form were seen at the time the number of organisms was diminishing most rapidly. Under similar circumstances, Cohn and Kornblith[31] found that "swollen, puffed-up, dumbbell-shaped or irregularly outlined ball-like forms" of gonococci appeared from one to five hours after the beginning of treatment.

Treponema pallidum.—Changes in the length of spirochetes obtained from patients under treatment with penicillin were first observed in this laboratory by H. G. Sleeper. During the examination by dark field illumination of material collected from the surface of chancres or from eroded papules of secondary syphilis it was found that the relative distribution of long and short forms of the spirochete varied after the beginning of treatment in such a way as to suggest that the changes observed were related to the effect of penicillin.

Within ninety minutes after the first injection of 20,000 units of penicillin there was a relative increase in the number of long forms of the spirochete. The increase was progressive within limits until organisms could no longer be found in the dark field preparations. In 1 instance, at two and a half hours after the first injection of 20,000 units of penicillin the ratio of long to short forms increased from 1 to 22 to 1 to 5, and in a second case after six hours of treatment, when the patient had received a total of 40,000 units, the ratio of long to short forms was 1 to 3 where originally it had been 1 to 10. No long forms were found before treatment in a third case, but three hours after 20,000 units of penicillin was administered there were two long forms to each short form. Altogether 5 patients have been studied, and in each the behavior of the spirochetes was similar.

The short forms were from 7 to 12 microns in length, while the long forms were from 14 to 22 microns. The long forms were in general less motile than the short forms and were occasionally angulated at the middle. At the point of angulation some organisms showed a small zone of thickening. In other instances it looked as if two short forms were hooked together.

As this phenomenon has attracted the attention of several observers in the laboratory, it apparently occurs with a certain degree of regularity and is probably significant.

In the light of the changes in form of bacillary organisms following contact with penicillin, one wonders whether the elongation of the spirochetes found in these cases may not be an indication of excessive growth and delayed cellular division. Although the mode of division of Treponema pallidum remains conjectural, one might assume from the increase in the number of long forms and the alteration in contour at the point of angulation which was observed in some of the long forms that the organism may possibly divide by binary fission.

INHIBITION OF PENICILLIN ACTION

The growth inhibiting properties of penicillin may be inactivated, or even destroyed, by substances of microbial origin. A fundamental understanding of such inhibitors and the mode of their action might shed some light on the mechanism whereby penicillin affects bacterial growth. The mode of action of the sulfonamides was indicated by the discovery that a substance contained in yeast, later identified as para-aminobenzoic acid, inhibits the action of sulfonamides on susceptible organisms.[32]

The existence of an inhibitory substance specific against penicillin was first demonstrated by Abraham and Chain,[33] who found that Escherichia coli, a gram-negative organism insensitive to penicillin, contained an enzyme-like substance which destroyed the growth inhibiting property of penicillin. This substance they called penicillinase. It was found, however, that penicillinase is not the sole factor determining the sensitivity of an organism to penicillin; in fact, penicillinase may be found in organisms sensitive to penicillin. Furthermore, an increase in tolerance to penicillin need not be accompanied by the production of penicillinase.[34] It is of interest, nevertheless, that most organisms commonly recognized as pathogens do not produce penicillinase, regardless of their sensitivity or insensitivity to penicillin.

Kirby[35] has reported the finding of a penicillin-destroying staphylococcus as a contaminant in a culture of Aspergillus flavus, and also a highly potent inactivator from a strain of penicillin resistant staphylococcus obtained from clinical sources, presumably the product of bacterial metabolism.

As the development of sulfonamide resistance by some strains of staphylococcus is related quantitatively to the production of para-aminobenzoic acid, these observations may have some significance as related to the possible mode of action of penicillin. In general, however, there is as yet little evidence to suggest the pos-

sibility of competitive enzyme systems as a basis for the action of penicillin.

A number of workers have succeeded in developing penicillin resistant strains of bacteria by cultivation in increasing concentrations of penicillin, but the nature of this acquired resistance is unknown.[34] Strains of coagulase positive staphylococci are occasionally identified which possess a natural resistance to penicillin, and others may acquire a temporary resistance.[36] Certain lots of clarase, a diastatic enzyme preparation, may inactivate penicillin. The potency of this substance was attributed to the presence of bacterial products, especially of Bacillus subtilis.[37]

Penicillin can also be inactivated by various sulfhydryl compounds, among them thioglycolic acid and cysteine. This has brought Cavillito and Bailey [38] to believe that the main mode of action of many antibiotic substances rests in their ability to interfere with the normal function of sulfhydryl groups in bacterial metabolism. When penicillin was brought in contact with an excess of neutralized cysteine hydrochloride, it rapidly lost its antibiotic activity.

Inactivation by cysteine may involve any one or more of the reactive groups in the cysteine molecule, namely the amino, the carboxyl and the sulfhydryl groups. As several of the amino acids (aminoacetic acid, cystine, methionine and serine) did not modify the activity of penicillin, and as cysteine was a more potent inactivator than thioglycolic acid, Chow and McKee [39] came to the conclusion that the inactivation by cysteine may involve both the sulfhydryl and the amino groups of the cysteine molecule.

Inhibition of antibiotics other than penicillin by certain sulfhydryl compounds has been repeatedly demonstrated. Of particular interest in this connection is the work of Geiger and Conn.[40] These workers studied the effect of cysteine and thioglycolate on clavacin and penicillic acid, as well as on some other alpha, beta unsaturated ketones which were shown to have antibacterial activity. Both of these reducing agents diminished the antibacterial activity of those ketones with which a chemical reaction involving the sulfhydryl group occurs (as shown by the disappearance of the nitroprussic acid test for — SH). Similar results were obtained by Colwell and McCall,[41] who showed that the antibacterial action of menadione (2-methyl-1, 4-naphthoquinone), as well as that of its 3-chloro and 6-methyl derivatives, could be suppressed by thioglycolate and cysteine. These three substances were shown to react with — SH compounds. In contrast to these results, however, the antibacterial activity of 2-methyl-3-methoxy-1, 4-naphthoquinone remained unaffected by cysteine, and no evidence for a reaction between these two substances in vitro could be obtained.

The facts just summarized can be explained by assuming that the inhibition of antibiotics by sulfhydryl compounds occurs as the result of a chemical reaction involving the two substances and leading to the formation of an inactive reaction product. They do not require the hypothesis that the action of the inhibitor is the restoration of normal equilibrium conditions to an enzyme system involving — SH compounds, which was previously disturbed by the antibiotic. Indeed, the results obtained by Colwell and McCall with 2-methyl-3-methoxy-1, 4-naphthoquinone, as well as some of the data of Geiger and Conn, are in direct contradiction to this view.

The antibacterial action of the quinones is of interest in this connection because of the presence of the quinone structure in some antibiotic agents. The synthetic menadione was shown to be bacteriostatic and bactericidal for both gram-positive cocci and gram-negative bacilli.

The similarity of the effects of sulfhydryl compounds on penicillin and the arsenicals may be indicative of a possible similarity in the modes of action of the two types of antispirochetal agents. It is important to note, however, that significant differences exist with respect to such effects. While the inactivation of penicillin by cysteine proceeds slowly, the addition of this substance to suspensions of Treponema pallidum exposed to the action, for example, of arsphenamine results in the immediate inhibition of the antispirochetal action. The fact that the arsenicals can be regarded as general protoplasmic poisons, while penicillin is not, may also be an indication of the essentially dissimilar nature of their respective modes of action.

ADAPTATION OF MICRO-ORGANISMS TO PENICILLIN

The phenomenon of induced bacterial resistance to the sulfonamides has been adequately demonstrated in connection with gonococcic infections in man.[21] Adaptation of the gonococcus to the sulfonamides, however, does not affect its sensitivity to penicillin, so that sulfonamide resistant infections are readily responsive to treatment with penicillin.

It is possible by suitable laboratory procedures to increase the tolerance of bacteria to penicillin. Abraham and his associates [17] increased the resistance of a strain of Staphylococcus aureus as much as a thousand fold by subculturing at increasing concentrations of penicillin. McKee and Houck [42] increased the resistance of a staphylococcus to a point six thousand times as high as that of the parent strain by sixty serial passages through concentrations of penicillin barely inhibitory to growth. Neither Streptococcus pyogenes nor the pneumococcus was so readily altered in tolerance as was the staphylococcus. Increase in resistance was accompanied by a corresponding loss of virulence of the organisms tested. This is in contrast to the sulfonamide resistant cultures which retain their virulence.

The increased tolerance to penicillin as well as the decreased virulence of the organisms apparently was a permanent characteristic. It was unaffected either by passage through susceptible animals or by rapid culturing in blood broth or by two months' storage. The organisms made resistant to penicillin retained their sensitivity to the sulfonamides, gramacidin, gliotoxin and aspergillic acid.

There is also some evidence which would indicate that bacterial resistance to penicillin may be increased

in animals,[43] but thus far the development of resistance in man has been of minor importance.[36]

Mechanism of Bacterial Adaptation.—Studies on the tolerance of various strains of the gonococcus to sulfathiazole have furnished some indication of the way in which this organism has acquired an increased resistance to the sulfonamides.

According to Lankford[44] there is considerable evidence that naturally resistant strains of the gonococcus have been selected by the gradual elimination of the more susceptible organisms through treatment with the sulfonamides. The opportunity of selection was afforded by a wide range in the sensitivity of the gonococcus. As a consequence, the naturally resistant variants have survived to propagate the infection. As the process of elimination has continued, gonococcic infections have shown a steadily increasing tendency to become sulfonamide resistant.

Whether this theory fully explains the phenomenon or whether some subtle alteration in the metabolism of the bacterial cell may contribute to the increase in resistance is a question which has not been answered.

Spirochetal Adaptation to Penicillin.—An increased tolerance to penicillin of a virulent strain of Treponema pallidum has been reported by Dunham, Hamre, McKee and Rake.[11] Organisms recovered from a rabbit experimentally infected with the Nichols stain of Treponema pallidum and treated with amounts of penicillin insufficient to destroy the infection exhibited an increased resistance as measured by their motility. In tests with the original strain, 1,600 units of penicillin per 0.8 cc. immobilized from 62 to 81 per cent of the spirochetes, but only 6 to 18 per cent of those organisms recovered from the insufficiently treated animals were immobilized.

While these observations are of considerable interest, the problem in general of the resistance, or adaptation, of Treponema pallidum to therapeutic agents, whether arsenical or antibiotic, awaits further investigation for its ultimate solution. Essentially, very little is known of the habits of Treponema pallidum; its constitution, its mode of reproduction, as well as its entire life cycle are yet to be defined.

There are individuals with syphilitic infections which are resistant to treatment, as evidenced chiefly by infectious or serologic relapse. This is true of the more conventional therapeutic agents, such as the arsphenamines, and it is also proving to be true of penicillin.

Whether this resistance to treatment is the result of an infection with organisms of high native tolerance to the therapeutic agent or whether the native tolerance of the spirochete can be increased by exposure to subcurative amounts of the therapeutic agent are still unanswered questions. There is no knowledge of the relative sensitivity of various strains of Treponema pallidum as there is of many of the pathogenic bacteria. One would expect, however, that variations do exist and that they may be important factors in the individual's response to treatment. Nevertheless, in the interpretation of the failures of treatment it is necessary to consider the fact that the resistance of the host may play an equally, or even more, important part in the response to treatment than may the sensitivity of the infecting organism.

PENICILLIN TREATMENT OF THE SYPHILITIC PREGNANT WOMAN

NORMAN R. INGRAHAM Jr., M.D.; JOHN H. STOKES, M.D.;
HERMAN BEERMAN, M.D.; JOHN W. LENTZ, M.D.,
and
VIRGENE S. WAMMOCK, M.D.
Philadelphia

This report supplements our observations recorded in THE JOURNAL in the fall of 1944.[1] In general, our enlarged experience has tended to confirm the initial impression that sodium penicillin given by intramuscular injection is very satisfactory treatment for the syphilitic pregnant woman to prevent congenital infection of the fetus and that it may rapidly become the treatment of choice in this condition. Considerable progress has also been made in arriving at a satisfactory regimen for the infant infected with syphilis. The latter problem has seemed considerably more complex to work out than has been the treatment of syphilis in the adult with penicillin, largely because of the severity of the disease frequently encountered in the newborn in contradistinction to the adult, and because of the theoretical dangers inherent in the injudicious use of a rapidly spirillicidal drug under such circumstances. This study is still in progress and much is yet to be learned in the application of penicillin to both of these phases of syphilis. Nonetheless, as the material is accumulating a conservative appraisal of our existing knowledge seems worth while. The present paper deals with our increasing experience in the management of the syphilitic pregnant woman. Our advanced knowledge in the care of the syphilitic infant will be the subject of a separate report.

PENICILLIN TREATMENT OF THE PREGNANT WOMAN

Material.—To date we have treated 49 pregnant women with penicillin. Forty of these are Negro and 9 are white. For the most part they are young primiparas with a recently acquired infection. The oldest pregnant woman we have treated with penicillin is 36, the youngest 15, the average age is 19 years, and 21 of the total are less than 20 years of age. Two of the patients had primary syphilis, 1 in the seronegative stage at the commencement of therapy; 24 had secondary syphilis and 19 had early latent syphilis (the duration of which was known to have been less than four years).[2] This type of material was selected for the most part because it would give the greatest expectancy of infection of the fetus if the treatment proved unsuccessful. Our experience also includes the treatment of 3 women with late latent syphilis (the duration of which was more than four years) and 1 case of late congenital syphilis, treatment of which was given for interstitial keratitis. In these instances pregnancy was an incidental finding and not the primary reason for

administration of penicillin treatment. The results of the outcome of these pregnancies are less useful in determining the value of penicillin in preventing transfer of the infection from mother to child.

Treatment.—Forty-six of the 49 patients had received no previous treatment for syphilis and 3 had received some treatment with arsenical and bismuth preparations prior to pregnancy but not during it. One of these last was the patient with congenital syphilis who had received injection therapy for her interstitial keratitis; the other 2 presented latent syphilis and had received only a few weeks of treatment considerably prior to conception, insufficient it was felt to influence materially the course of the disease.

Specific therapy during the pregnancy was with penicillin only, 10 patients receiving a total dosage of 1.2 million Oxford units of sodium penicillin and 30 receiving a total of 2.4 million Oxford units. The treatment of the remaining 9 patients was individualized and not according to a definite schedule. The drug has in every instance been administered intramuscularly in distilled water, in the cases first studied at four hour intervals, but more recently at three hour intervals. In the majority of instances the initial dosage has been reduced to about one-fourth the maximum dose for the first forty-eight hours; subsequent dosage has been from 20,000 to 50,000 Oxford units per injection. The total duration of treatment for the most part has been from seven to nine days, the length of the course being determined by the size of the initial dosage. In several instances the treatment was prolonged over a period of ten to twelve days. The treatment described, except for the lowered initial dosage, is similar to that used by Mahoney and his co-workers in the treatment of early syphilis in the adult and is in accord with the recommendations of the Penicillin Panel of the Subcommittee on Venereal Diseases, National Research Council.[3]

The type of treatment of the remaining 9 patients was as follows: Three (82, 105, 135) received a total dosage of 1.2 million Oxford units of sodium penicillin in four days. In 2 of these this dosage proved to be inadequate and retreatment with 2.4 million units in seven and one-half days was carried out in each instance. One patient (130) relapsed after receiving an initial dose of 2.4 million Oxford units in seven and one-half days and required two subsequent courses totaling 6.4 million Oxford units to control her disease. Four patients (326, 365, 367, 405) each received two courses of 2.4 million Oxford units of penicillin prior to delivery, because of failure of immediate serologic response. Our subsequent observations indicate that this retreatment may have been unnecessary. One patient (336) received 1 million units of penicillin, following which treatment was discontinued because of threatened abortion. This patient received an additional 1.2 million units three months later and prior to confinement. It should be pointed out that throughout the course of this study we have been more concerned in learning whether penicillin as such is effective in the prevention of congenital syphilis than in determining the exact or optimum dosage required. We have felt it better to give too much than too little of the drug and have not desired to experiment with smaller doses at great possible risk for the child. We have been guided by the doses which have been found effective in the treatment of early adult syphilis not complicated by pregnancy, have used the larger rather than the minimal dose and have retreated the patient on slight pretext.

Initial treatment with penicillin was given in various stages of the pregnancy: prior to the sixteenth week 4 cases, between the sixteenth and thirty-second week 26 cases, after the thirty-second week 9 cases. Since fetal infection is considered to occur any time after the sixteenth week and to become increasingly more probable as term approaches, the distribution of cases throughout the pregnancy as indicated should give a fair appraisal of the value of penicillin in any stage.

Treatment Reactions.—The only reaction of note encountered in the treatment of the syphilitic pregnant woman was threatened abortion. This type of complication was mentioned briefly in our previous article[1] on this subject as being in all probability a species of therapeutic shock and we are now able to give a little more light on the probable frequency of its occurrence. One patient (211) with early latent syphilis and in the fourth month of her pregnancy aborted on the fourth day after penicillin therapy was commenced. In this instance initial dosage had been 12,500 Oxford units every four hours for the first day and 25,000 units every four hours the next two days, at which time it was increased to 50,000 units per injection. Lower abdominal pain and spotting commenced on the second day. It was, of course, difficult to know in this instance whether the fetus was living when treatment was started or whether the outcome would have been the same if penicillin was withheld when first symptoms developed. In a later case (336) with secondary syphilis and also in the fourth month vaginal bleeding likewise developed on the second day after the commencement of treatment and persisted to the fifth day, when treatment was stopped. During this period the patient had received 1 million units of penicillin: 20,000 Oxford units every three hours for the first twenty-four hours and 40,000 units every three hours thereafter. Abortion did not occur, and she was retreated in the seventh month of her pregnancy with 1.2 million Oxford units in seven and one-half days without ill effect.[3a] Patient 287, a woman with early latent syphilis, delivered a macerated stillborn fetus seven days after the commencement of her penicillin treatment and two months prior to her calculated date of confinement. In this instance it was felt that the fetus was not living when penicillin was started, a circumstance which should always be carefully ascertained if possible in commencing antisyphilitic therapy in the pregnant woman. Two other patients in this series (39, 315) developed lower abdominal cramps, vaginal bleeding and signs of threatened abortion during the penicillin course, and 1 other patient (57) developed severe abdominal cramps without bleeding, necessitating considerable sedation and active gynecologic supervision. Milder forms of lower abdominal discomfort were not uncommon during the first twenty-four to forty-eight hours, often accompanied by a febrile Herxheimer reaction. We accordingly feel that the possibility of abortion is a very real threat to some pregnant syphilitic women treated with penicillin, to be anticipated and avoided by reduction of initial dosage for forty-eight hours, bed rest, sedation as necessary and temporary suspension of the penicillin if bleeding develops.

[3a] This mother subsequently proved not to be pregnant. It is not certain whether the woman miscarried following the initial course.

CLINICAL AND SEROLOGIC RESPONSE IN THE MOTHER

In all instances in which the mother had evidence of early syphilis at the start of treatment, these signs and symptoms have promptly disappeared. In only 7 instances; on the other hand, among the 40 pregnant women treated with penicillin who have thus far reached term had the blood serologic test for syphilis in the mother become negative before the baby was born. Considering the uniformly favorable ultimate outcome, to be given in more detail later, it may accordingly be concluded that a reversal to negative during the antepartum period is not necessary to obtain a normal infant.

The clinical and serologic follow-up of these cases was as outlined: A quantitative titered blood serologic test was made for syphilis reagin at the commencement of the penicillin treatment and at its completion. This test was repeated in two weeks and then at monthly intervals as long as positive. A complete physical inspection for evidence of surface lesions and a brief inquiry as to symptoms were made at each visit. After the blood test became negative it was repeated once at monthly intervals and then at three months intervals for the duration of the study. To the time of compiling this material 10 mothers had been observed for periods of one year or more after treatment with penicillin, 17 between six months and one year and 22 for less than six months. The average duration of follow-up after treatment is seven months, and 1 mother has been observed for seventeen months.

Only 20 of the 49 patients have developed persistently negative serologic tests. Time has seemed to be more a factor than dosage in bringing about these favorable results, since those which have been observed the longest are for the most part those who have received the smaller dosage (i. e. 1.2 million Oxford units). We, of course, have been unable to control the type, purity or spirillicidal value of the penicillin as such and, in fact, have used a variety of different lots and brands in these studies. The work of Dunham and Rake[4] indicates that such a consideration may be of more than passing importance. The time factor is shown in the accompanying table.

In the 1 instance in the table in which seronegativity was not obtained by the end of one year, the titer of the test is very low: less than 1 unit of syphilis reagin; in the six month to one year group 2 of the 13 cases still seropositive exhibit less than 1 unit of reagin. The average length of time from the start of penicillin treatment until a definite sustained drop was noted in syphilis reagin in the mother's blood serum as revealed by quantitative titered Kolmer, Wassermann and Kline tests was sixty days. The average length of time after penicillin until sustained seronegativity was obtained in the 20 cases which have thus far become seronegative was one hundred and ninety days. The most rapid reversal to complete and sustained seronegativity was in the single case which was seronegative but dark field positive at the commencement of treatment. This case (386) became temporarily positive with quantitative titer as high as 4 units of syphilis reagin during the course of penicillin therapy but reverted to negative by the twenty-second day and remained so. Of those cases which were definitely seropositive at the initiation of treatment the earliest sustained complete reversal to negative observed was on the sixty-fourth day, a case (350) of early latent syphilis treated with 2.4 million units of penicillin. The case (96, secondary syphilis treated with 2.4 million units of penicillin), which remained positive longest after penicillin but eventually reversed to sustained seronegativity was noted to have its first negative reaction on the three hundred and sixty-fifth day.

These results would seem to indicate that the pregnant syphilitic woman with early syphilis, treated with penicillin, may be expected to remain seropositive even though the treatment is apparently effective, for as long as six months to one year after the treatment is completed. The serologic response here noted is considerably slower than that recorded by Moore and the National Research Council's Penicillin Panel[5] for early syphilis as a whole. They found an apparent trend to serologic reversal in a period of about twenty days after the start of treatment as compared to sixty days in the present series. Further, when 1.2 million units of penicillin was used, the mean serologic response reached negativity at about the seventieth day as compared to the one hundred and ninetieth day in the present series. Whether this slower response is the result of biologic factors associated with pregnancy makes interesting speculation, but definite conclusions must await further observation. The total number of cases observed is small; the effective amount of "penicillin" for syphilis in the crude product awaits satisfactory standardization; variations in the sensitivity of the tests employed in various laboratories may all be playing as important a role in influencing this apparent tendency to delayed serologic response as is pregnancy itself.

Serologic Response of 49 Pregnant Women Treated with Penicillin

(For dosage range see text)

Period of Observation After Penicillin	Patients with Still Positive Serologic Tests		Patients with Negative Serologic Tests	
	Number	Per Cent	Number	Per Cent
1. More than 1 year............	1	10	9	90
2. Between 6 months and 1 year	13	76	4	14
3. Less than 6 months..........	15	65	7	35

CLINICAL AND SEROLOGIC RELAPSE IN THE MOTHER

Among the 49 cases there have been 2 which have relapsed clinically and 1 which has relapsed serologically. There have also been 4 cases, as already mentioned, that have been retreated because of failure to obtain any serologic response from the initial course of 2.4 million Oxford units of penicillin. Two of these retreated cases were of early latent syphilis (326, 367) retreated five and one-half months and four and one-half months after initial therapy. The other 2 were secondary syphilis (cases 365, 405) retreated four months and three months respectively after initial treatment.

To judge from the analysis in the preceding section, in each of these instances it may have been too soon to expect noticeable serologic response, and retreatment may have been unnecessary. Nonetheless with the child's life at stake we preferred to adopt a conservative attitude and to leave no stone unturned in obtaining a healthy infant. A very brief summary of the treatment and the serologic and clinical response in each of the relapsing cases follows:

Case 105.—*Relapsing secondary syphilis at time of delivery. Infant infected.*

A Negro woman aged 21 was diagnosed as having secondary syphilis and received 1.2 million Oxford units of sodium penicillin from May 24 to May 28, 1944. The titer of her blood serologic test to the quantitative Kolmer Wassermann technic was 128 units at the commencement of therapy. Her initial secondary eruption healed within ten days, but there was no reduction in the blood serologic test up to the time of confinement. She was delivered of a physically normal full term infant on September 23 but while on the delivery table was noted to have condylomata lata, which proved on subsequent study by dark field illumination to contain Treponema pallidum. She was given a second course of 2.5 million Oxford units of sodium penicillin, which served to heal her genital lesions, but there has still been no reduction in blood serologic titer to the time of the last test, June 1, 1945. Her infant had 64 units of syphilis reagin in its blood when born. This rapidly dropped to 2 units within the next seven weeks but then rapidly rose to 256 units. The roentgenogram of the infant's long bones was normal during the neonatal period but showed early osteochondritis at 6 weeks and advanced changes at nine weeks. Dark field positive skin lesions developed in the third month, and treatment with penicillin was commenced on the infant Dec. 20, 1944. The initial clinical response in the infant to penicillin was good, and his first negative blood serologic test was obtained June 1, 1945.

Case 130.—*Relapsing secondary syphilis four weeks after delivery. Infant apparently normal.*

A Negro woman aged 25 was treated for secondary syphilis with 2.4 million Oxford units of sodium penicillin in seven and one-half days starting June 15, 1944. The initial quantitative titer of her blood serologic test as determined by the Kolmer Wassermann technic was 32 units, which is lower than is usually obtained in active secondary syphilis. This declined immediately, being 8 units on July 6 and between 2 and 4 units in mid-August. On September 29 her blood serologic titer had risen to 64 units and she developed dark field positive surface lesions. On October 21 she received a second course of 2.4 million units of sodium penicillin and when serologic response was not evident an additional course of 4 million Oxford units of sodium penicillin was given over a period of six days (January 1945). Her blood serologic test for syphilis was negative for the first time May 21, 1945. Her infant was born Sept. 1, 1944 before her infectious relapse. He had a negative blood serologic test at the time of delivery and apparently escaped infection. He was separated from the mother during her infectious relapse period and was normal to physical and roentgenologic examination and had a negative blood serologic test when last examined, April 27, 1945.

Case 432.—*Early latent syphilis, treated in last week of pregnancy. Seroreiapse in mother. Infant apparently normal at two months post partum.*

A Negro woman aged 18 received 2.4 million Oxford units of sodium penicillin starting on March 20, 1945. Her pretreatment blood serologic titer was 128 units (Kolmer titered Wassermann). She was delivered of a clinically normal infant with 32 units of syphilis reagin in his blood stream on March 28, 1945. The infant's titer had dropped to less than 1 unit by May 11 and was completely negative on May 25. He was normal to physical examination and a roentgenogram of the long bones was negative through this period. There is still some possibility that this infant may be syphilitic but the chances are remote: statistically not greater than 5 per cent. The mother's blood serologic titer receded rapidly following her penicillin treatment. It was significantly reduced below the initial 128 units on March 31 and was completely negative on May 11. Since then it has increased rapidly and on May 26 and June 1, 1945 was between 128 and 256 units, as high as at any period in our observation. Retreatment has been ordered but not yet carried out at the time of this writing. She has shown no surface lesions during this period.

Twenty-seven of our pregnant women have been observed for periods of more than six months after their penicillin treatment. Limiting the study to this group, the clinical and serologic relapse rate among the mothers has been 3 in 27, or 11 per cent.

SYPHILIS STATUS OF THE NEWBORN INFANTS

Of the 49 women in this study treated with penicillin, 39 have at the time of compilation of these data reached the termination of their pregnancy. One woman has completed two pregnancies during the course of this study. Of these 40 confinements 37 have resulted in the birth of apparently normal children, 1 in an abortion prior to the sixteenth week and 1 in a miscarriage after the midpoint in the pregnancy. These last 2 are cases 211 and 287, described in a previous section, and could not be attributed to penicillin failure in the strict sense of the term. Only 1 living syphilitic child was born.

The postnatal medical follow-up has been active and has consisted in the following: At the time of birth, a cord Wassermann test was taken and in many instances dark field examination of the umbilical vein was performed.[6] The latter procedure was carried out routinely when the study was started, but as it became apparent that penicillin was an effective spirillicidal agent in the pregnant woman and that the infants were uniformly normal it was felt that this procedure was superfluous and it was discontinued. The blood serologic test was repeated uniformly on the infant within the next week, before discharge from the maternity nursery. A roentgenogram of the long bones of one upper and one lower extremity was also carried out routinely at about the fifth day. If the blood serologic test for syphilis obtained on the infant in the maternity nursery was positive, this test was repeated at the age of 3 weeks and weekly thereafter until it became definitely negative or, in the syphilitic infant, until a definite increase in titer was observed. A roentgenogram of the long bones was repeated on all infants at the age of 6 weeks. Infants seronegative at birth and seropositive infants who subsequently became seronegative were uniformly subjected to a blood serologic test at the age of 1 month, 2 months, 3 months and 6 months and then at three month intervals for the duration of the study. Complete physical examinations were performed at each visit.

Since this is an interim report in a continuing study, all infants born have not as yet completed a satisfactory term of postnatal observation. The adequacy of this aspect of the study may be gaged by the following figures: The maximum duration of postpartum follow-up of the infant is three hundred and eighty-eight days and the average duration is five months. Three infants have been followed more than one year, 11 between six months and one year, 13 between two and six months and 11 for periods of less than two months. It is our feeling that those infants followed for one year have had their status with respect to syphilis definitely established; for the infants followed for six months or more the diagnosis normal (or nonsyphilitic) is presumptively correct; for infants followed for more than two months with the procedure as outlined it is unlikely that the diagnosis will have to be modified; but a follow-up period of less than two months must be considered completely inadequate in determining the syphilis status of the infant.

---

[6] Ingraham, N. R., Jr.: Congenital Syphilis: Diagnosis by Means of Dark Field Examination of Scrapings from the Umbilical Vein, J. A. M. A. **105**: 560 (Aug. 24) 1935.

Fourteen (38 per cent) of the 37 infants born alive and physically normal to date had positive blood serologic tests at the time of delivery. This percentage is somewhat higher than in previous series reported from these same clinics,[7] which have ranged from 6 to 16 per cent. It is probably accounted for by the fact that the mothers all had early syphilis and in most instances still showed relatively high titers to the quantitative tests employed at the time of delivery. In every instance in which the infant was positive, the mother was also seropositive at the time of delivery. The degree of positiveness in the infant's blood in quantitative Kolmer, Wassermann and Kline units has ranged from 32 to less than 1. Excluding the only syphilitic baby, in those infants which have been followed for more than one month postnatally the initially positive tests reverted to complete negativity in twenty-nine days on an average. Only 3 cases required more than one month to become normal: case 124, thirty-two days; case 301, fifty-one days; case 432, fifty-eight days. The clinical course of the only syphilitic infant appearing in this series thus far is given in the detailed report of case 105. Again, except for the syphilitic infant, all roentgenograms of the long bones performed in the nursery or at 6 weeks or later have been normal. Physical examinations have shown no evidence of syphilis.

The infant offspring in case 25 died at the age of 7 months from an acute febrile illness the exact nature of which was not determined but which could not apparently be attributed to syphilis. The mother, a Negro woman aged 18, had received 1.2 million Oxford units of sodium penicillin in divided dosage over a period of seven and one-half days, for dark field positive, seropositive secondary syphilis from Jan. 10 to 18, 1944. Her clinical response was normal. She gave birth to an apparently normal child on April 13, 1944 who had 16 units of syphilis reagin in his blood stream during the immediate neonatal period. This test had become negative by the twentieth day and remained negative to repeated testing thereafter. The physical findings in the infant and the roentgenograms of the long bones were likewise normal. In the latter part of October of the same year the infant was returned to the hospital with an acute febrile illness and died within three days on October 24. An autopsy did not reveal the exact cause of death, but no evidence of syphilis was revealed to detailed gross and microscopic examination of the organs, including silver stain for Treponema pallidum. It was felt that this death was not caused by syphilis and that it did not constitute a penicillin failure.

Case 13, contained in table 1 of our previous report,[1] is of particular interest because the mother gave birth to a second apparently normal infant on March 29, 1945, exactly one year after the birth of her first child, which is likewise still normal. This 29 year old Negro woman was treated for secondary syphilis with 1.2 million Oxford units of sodium penicillin in seven and one-half days commencing Dec. 16, 1943. She has received no treatment for her syphilis since and went through her second pregnancy without specific therapy. The blood serologic tests and roentgenograms of the infant born March 29, 1945 have remained normal to June 12, 1945. Although follow-up of the infant (two and one-half months) postnatally could not as yet be considered adequate, the preliminary indications are that the mother has been cured of her disease by this single course of penicillin and that treatment in subsequent pregnancies is probably unnecessary.

SUMMARY OF PRESENT STATUS OF KNOWLEDGE IN TREATMENT OF SYPHILITIC PREGNANT WOMEN WITH PENICILLIN

In the material available at the time of the compilation of these data, among 27 infants followed for periods of more than two months postnatally, many for much longer periods, 24 born of mothers with early syphilis treated with penicillin during their pregnancy, only 1 has been shown to be infected with syphilis. This success, which approaches 97 per cent if borne out by further observation as the study progresses, indicates a result at least equal to that obtained by the arsenical-bismuth regimen now generally employed in the prevention of congenital syphilis. The treatment may, moreover, be given in a single course over a short period and is apparently curative of the mother's disease at the same time as it prevents transfer from mother to fetus in utero. We cannot be certain at this writing whether this success is as applicable to the commonly occurring latent syphilis of unknown duration in the pregnant woman as it is to early syphilis in pregnancy, since our experience covers to date almost exclusively the latter. It is now demonstrated through laboratory evidence[8] that penicillin will pass from the maternal to the fetal blood stream at term. There is some indirect clinical evidence in the present study to indicate that penicillin may traverse the placental barrier earlier in the pregnancy in that 9 of the women in the present series were treated after the thirty-second week of the pregnancy with uniformly good results when the possibility of infection of the fetus would be presumably high. Since the fetus may be infected anytime after the sixteenth week, the permeability of the placenta to penicillin from the fourth to the ninth lunar month is a critical issue in the prevention of congenital syphilis by a single course of the drug during pregnancy.

Although it is yet not possible to draw definite conclusions as to the preferred method of treatment of the pregnant woman with syphilis, our experience with penicillin is such as to give definite impressions. Our only treatment failure with the infant occurred in a patient who received her total therapy in a four day period. We feel that treatment should be prolonged for at least seven and one-half days, as is now usually recommended for early syphilis in the adult, and possibly a little longer. There is no real indication that 2.4 million Oxford units given over the longer interval (seven and one-half to twelve days) is any more successful in preventing congenital syphilis and in curing the disease in the mother than is 1.2 million units in seven to nine days. Our 2 other initial treatment failures in the mother have both occurred with the use of 2.4 million units total dosage, 1 of the women with symptomatic early, the other with latent syphilis. In general, nonetheless, we have felt that, since inadequate dosage may be serious for the infant, it is better to err on the side of giving too much rather than too little penicillin.

R., Jr.: The Management of Syphilis in the Newborn and During Early Childhood, Pennsylvania M. J. **42**: 920 (May) 1939.

[8] Herrell, W. E.; Nicholas, D. R., and Heilman, Dorothy H.: Penicillin: Its Usefulness, Limitations, Diffusion and Detection, with an Analysis of 150 Cases in Which It Was Employed, J. A. M. A. **125**: 1003 (Aug. 12) 1944. Greene, H. J., and Hobby, G. L.: Transmission of Penicillin Through Human Placenta, Proc. Soc. Exper. Biol. & Med. **57**: 282 (Nov.) 1944.

Specifically, if there were no complications we would use a total dosage of 2.4 million Oxford units of sodium penicillin given over a period of eight to nine days as follows: 10,000 units in each three hour injection intramuscularly for eight injections and 20,000 units in each three hour injection for the next eight injections, followed by fifty-four three hourly injections of 40,000 units each. Complications arising from therapy, from pregnancy or from syphilis require strict individualization. Since our results have been satisfactory without the supplementary use of other types of chemotherapy for syphilis, we can see no reason at this time for employing any drug but penicillin provided the initial response is satisfactory.

CONCLUSIONS

The following conclusions are based on a study still in progress and are subject to modification as additional information is accumulated. They do, however, represent our present working knowledge of the treatment of the pregnant woman with early syphilis with sodium penicillin by intramuscular injection and as such are of value as an interim report.

1. One syphilitic infant has occurred among 37 syphilitic pregnancies, treated with penicillin, which have reached term. In 27 of these cases the infant has been followed for periods greater than two months postnatally and the presumptive evidence that the infant is normal is good. This represents a degree of success equal to if not greater than that obtained with the arsenical-bismuth regimens at present widely employed.

2. Either 1.2 million or 2.4 million Oxford units total dosage seem satisfactory for the pregnant woman, though the larger dosage is preferred. It is recommended that the dosage be reduced to one fourth during the first twenty-four hours and to one half during the second twenty-four hours to reduce the possibility of threatened abortion from therapeutic shock and that the duration of treatment be prolonged to eight or nine days.

3. The serologic response to penicillin treatment of the pregnant woman is apparently considerably slower than the average for early acquired syphilis in the adult. It is not necessary, on the other hand, that the mother be seronegative at the time of confinement in order for the infant to be normal.

4. As a result of our continued use of penicillin in the treatment of the pregnant woman with early syphilis, we are confident that this drug represents a distinct advantage in that it is a convenient, safe and effective mode of therapy.

PENICILLIN IN PREVENTION OF PRENATAL SYPHILIS

MARY STEWART GOODWIN, M.D.
and
JOSEPH EARLE MOORE, M.D.
Baltimore

Ingraham and his associates[1] have recently published a communication dealing with penicillin treatment of the syphilitic pregnant woman. Their report deals with 49 pregnant women, of whom, at the time of treatment, 26 had manifest early (primary or secondary), 19 early latent (no symptoms; infection of less than four years' duration), 3 late latent (more than four years' duration) and 1 congenital syphilis. At the time of their writing, 39 of these women had delivered a total of 40 infants (one of them 2 pregnancies).[2]

The spectacularly favorable results in the prevention of syphilis in the fetus reported by Ingraham's group is confirmed by our own material. We have treated 31 mothers, all of whom had early infectious (primary or secondary) syphilis at the time of treatment, all of whom have now delivered and all infants are apparently normal. Our own material will be compared with that of Ingraham and his group in a series of tables, with accompanying comment.

TYPE OF SYPHILIS IN THE MOTHER

The published material of the Philadelphia group is not entirely comparable with that in Baltimore. Of their 49 patients only 26 had lesions of early syphilis. The Baltimore group has up to this point deliberately avoided the penicillin treatment of pregnant women with latent syphilis, confining itself entirely to manifest early (primary or secondary) syphilis in the mother. This limitation of the clinical material for the purposes of evaluation of penicillin was undertaken because of (*a*) the practical certainty of infection of a fetus born of a mother with outspoken early syphilis and (*b*) the lack of such certainty in infants born of mothers with latent syphilis. Though the exact percentage probabilities have never been accurately defined, it is a well known fact that mothers with latent syphilis may deliver normal nonsyphilitic children, the risk of syphilis to the child being roughly in inverse proportion to the duration of syphilis in the mother (Kassowitz's law).[3] We therefore proceeded to test the efficacy of penicillin in the prevention of infantile congenital syphilis in that group of cases in which the probability of infection of the fetus was largest.

Through Ingraham's[4] courtesy we are enabled to present the Philadelphia mothers with early syphilis (status as of Sept. 10, 1945) in exact parallel with our own cases, thus adding to the value of the total series by doubling the numbers and eliminating confusion from the inclusion of latent syphilis in the published Philadelphia material.

From the Johns Hopkins University and U. S. Public Health Service Venereal Disease Research and Post Graduate Training Center, Baltimore.

The work described in this paper was done under a contract, recommended by the Committee on Medical Research, between the Office of Scientific Research and Development and the Johns Hopkins University.

PREVIOUS TREATMENT GIVEN TO THE MOTHER

None of the Philadelphia patients with early syphilis and 2 of the 31 Baltimore patients had received previous antisyphilitic treatment (table 1). One of these was a Negro woman aged 19 who had primary syphilis in November 1943. Between November 1943 and April 1944 she had received thirty intravenous injections of oxophenarsine hydrochloride (mapharsen) totaling 1,800 mg. and eight intramuscular injections of metallic bismuth totaling 1.04 Gm. Her blood serologic test remained negative from May 1944 to July 1944. During July 1944 her sexual partner had an infectious relapse of secondary syphilis, and the patient's serologic test again became positive with a quantitative titer of 16 units, and dark field positive genital lesions occurred. It was felt that she had either a reinfection or a relapse, probably the former. She was retreated with 1.2 million units of penicillin in August 1944 in the fourth month of pregnancy.

The second patient was a Negro woman aged 19 who at 4 months of age was observed in the Johns Hopkins Hospital to have a positive serologic test for syphilis and outspoken signs of congenital syphilis, including snuffles and a generalized skin eruption. She received irregular treatment over a period of eight years, totaling ten doses of sulfarsphenamine, seven doses of neoarsphenamine and eight doses of bismuth. Her spinal fluid examination was negative at the age of 17 years, and her blood serologic tests were repeatedly negative during eighteen years after the initial diagnosis of congenital syphilis was made. She apparently had a reinfection [5] when she was found in February 1944 to have secondary syphilis with dark field positive mucosal lesions and a quantitative blood serologic titer of 256 units. Not pregnant at this time, she was given 800,000 units of penicillin (in eight doses of 100,000 units each at twelve hourly intervals) for secondary syphilis. Her blood serologic titer declined to 1 unit six months after completion of this treatment; but one month later it relapsed to 64 units. At this time (October 1944) she was one month pregnant and was retreated with 3.6 million units of penicillin.

THE DOSAGE OF PENICILLIN

In the Philadelphia series 24 mothers received a single course of penicillin only; 2 received multiple courses during pregnancy. In the Baltimore series the corresponding figures are twenty-eight single courses and three multiple courses. The total dosage range of the single courses in both Baltimore and Philadelphia groups is comparable, the majority of patients having received from 1.2 to 2.4 million units. In the Baltimore group 3 patients were given only 600,000 units and 4 others a total of 3.6 million units.

In the Philadelphia series 2 patients were retreated during pregnancy. Each of these received 2.4 million units of penicillin as a first course in the fourth and fifth months of pregnancy respectively. One was retreated with a second course of 4.8 million units in the ninth month of pregnancy, four months after the first course; the other received a second course of 2.4 million units in the seventh month of pregnancy, three months after the first course. In each case retreatment was given because of failure of immediate serologic response. In each case the infant was born alive and apparently normal.

All of the 3 Baltimore patients to whom retreatment during pregnancy was given had serologic relapses following an initial course of penicillin. One of the 3 was initially treated with 600,000 units, 1 with 800,000 units and 1 with 2,400,000 units of penicillin. All 3 were in the last trimester of pregnancy when they developed serologic relapse.

These relapses in the Baltimore group occurred in the 3 patients who received second courses of penicillin as described in the previous paragraph.

The first patient had an initial course of penicillin of 2,400,000 units (20,000 units every three hours for 120 doses). She had dark field positive lesions of secondary syphilis diagnosed in the fourth month of pregnancy. She was seronegative four and five months after the first course of penicillin and then at six months after treatment (and in the last month of pregnancy) developed a serologic relapse to 16 units. She was then retreated with 1,560,000 units of penicillin. On completion of this amount of penicillin the patient, being at full term, delivered spontaneously. Penicillin was continued after delivery to a total of 4,640,000 units in this second course.

The second patient received 800,000 units in the initial course of penicillin for primary syphilis with dark field positive lesions at a time when she was about two weeks pregnant. She was serologically negative four months after penicillin treatment and developed serologic relapse seven months after treatment (with a titer of 2 units). She was retreated with 3,600,000 units of penicillin in the seventh month of pregnancy.

The third, and last, of the Baltimore group received 600,000 units in the second month of pregnancy for secondary syphilis with dark field positive lesions. Her serologic titer declined to 2 units two months after treatment and then rose in the third and fourth month to 16 units. She was considered to have a serologic relapse and was retreated with 1,200,000 units in the sixth month of pregnancy.

[5] This is an additional example of reinfection in treated congenital syphilis not previously reported from this clinic in the two papers by Hahn (Am. J. Syph., Gonor. & Ven. Dis. 25: 200, 1941) and Allison (ibid. 26: 212, 1942).

DURATION OF PREGNANCY AT THE TIME OF PENICILLIN TREATMENT

As is indicated in table 1 of the combined Philadelphia and Baltimore series 14 mothers were treated before the sixteenth week of pregnancy, to 31 treatment was given between the sixteenth and thirty-second weeks, and in 12 the duration of pregnancy was thirty-two weeks or longer at the time of treatment. As Ingraham and his group point out, "since fetal infection is considered to occur any time after the sixteenth week and to become increasingly more probable as term approaches, the distribution of cases throughout the pregnancy, as indicated, should give a fair appraisal of the worth of penicillin in any stage [of pregnancy]."

ABORTION DURING TREATMENT (THERAPEUTIC SHOCK? DIRECT PENICILLIN ACTION?)

While Ingraham and his associates observed two actual and two threatened abortions among their 49 women treated, three of these accidents occurred in patients with latent syphilis. A similar accident was not observed in any of the 31 Baltimore cases, all with early syphilis (table 2). The Philadelphia authors have interpreted this phenomenon as possibly due to therapeutic shock (Jarisch-Herxheimer reaction) and are inclined to advise a reduction of initial penicillin dosage for the first forty-eight hours of treatment of pregnant women. The fact that 3 of their 4 actual and threatened abortions were in patients with latent syphilis, coupled with the total absence of phenomenon in 25 of their 26 and in our own 30 patients with early syphilis, tends, we believe, to weaken this argument. Therapeutic shock from penicillin is considerably more frequent and more intense in males and nonpregnant females with early than in those with late syphilis. If this reaction were a factor in actual or threatened abortion, one would naturally expect its incidence to be high in early syphilis of the mother (1 example in 57 cases of the combined series) and low in latent infections of longer duration (though actually 3 examples in 23 such women in the published Philadelphia paper). We are therefore not inclined to share the opinions either that abortion, actual or threatened, is a frequent evidence of therapeutic shock in penicillin treated mothers or that great initial caution in treatment is necessary or desirable to prevent this treatment reaction.[5a]

TABLE 2.—*Outcome of Penicillin Treatment in Mothers*

(As of Sept. 10, 1945)

Authors	Abortions		Relapses in Mothers		No. of Mothers Followed Serologically for 6+ Mos. After Penicillin Treatment	Of These, Mother's Blood †	
	Actual	Threatened	Clinical	Serologic		Seronegative	Still Positive
Ingraham and others	0	1	2*	0	22	12	10
Goodwin and Moore	0	0	0	3‡	24	20	4
Total	0	1	2	3	46	32	14

* After 1.2 and 2.4 million units, respectively.

† For discussion, see text.

‡ Two after 800,000 and one after 2.4 million units.

Leavitt,[6] who has observed 2 actual and 6 threatened abortions among 21 pregnant syphilitic women (type of syphilis in the mother not stated), suggests an alternative explanation for the phenomenon. Seven of his 8 reacting patients were treated with the same lot of penicillin. This fact and "the oxytocic action of ergot, a biologic product of another mold (Claviceps purpurea)" suggest to him that penicillin or some impurity contained in commercial penicillin may exert a directly stimulating effect on the contractility of the uterine musculature.

If one combines the total of 101 women treated by Ingraham and his group, Leavitt and ourselves, there were 4 actual and 7 threatened abortions. These figures are not statistically impressive as incriminating penicillin as a cause of abortion since it is a well known fact that in obstetrics that approximately 10 per cent of all pregnancies in normal nonsyphilitic, nonpenicillin treated women end in spontaneous abortion (usually early in pregnancy) and perhaps another 5 to 10 per cent have threatened abortions.[7] The abortions, actual and threatened, among these penicillin treated syphilitic women do not equal the normally expected incidence of spontaneous abortions.

The solution of the problem as to the effect of penicillin in producing abortion is readily obtainable from simple [illegible] linical studies now in progress. [illegible] to be gained from these studies, we feel that the suggestion that penicillin has abortifacient effects is unwarranted by the facts.

CLINICAL AND SEROLOGIC RELAPSES IN THE MOTHER

In the Philadelphia group (table 2) one Negro woman with secondary syphilis who received 1.2 million units of penicillin during the fifth month of pregnancy was found to have a clinical relapse at the time of delivery. Since the infant born of this mother was the only one in the entire series who has so far developed congenital syphilis, it is important to note that in the interval between treatment and delivery the titer of the mother's blood serologic test did not decline. This fact suggests that, in early syphilis of the mother at least (as contrasted to latent infections), failure of maternal serologic response to penicillin treatment administered early in pregnancy is an indication for retreatment of the mother before delivery. It is possible that even this single failure of treatment in the infant might have been prevented by retreatment of the mother.

A second Philadelphia Negro woman with secondary syphilis, treated with 2.4 million units during the seventh month of pregnancy, developed infectious clinical relapse four weeks after the delivery at term of a normal infant.

The 3 Baltimore maternal relapses, all serologic only, without clinical evidence of infectious relapse, have been described in the paragraph dealing with retreatment of the mother. With regard to the question of retreatment, it is, we think, significant that the infants born of these 3 relapsing and retreated mothers, and of the 2 retreated Philadelphia mothers, were all normal.

SEROLOGIC PROGRESS OF THE MOTHERS

As indicated in table 2, only 12 of the 22 Philadelphia patients followed for six months or longer after treatment have become seronegative, whereas 20 of the 24 Baltimore patients followed for comparable periods of time have reverted to seronegativity.

[5a] Since this paper was submitted for publication, Speiser and Thomas (J. Ven. Dis. Inform. 27: 20 [Jan.] 1946) have likewise noted the absence of abortifacient effect of penicillin in 149 pregnant women with early syphilis treated by them.

[6] Leavitt, H. M.: Clinical Action of Penicillin on the Uterus, Ven. Dis. Inform. 26: 150 (July) 1945.

[7] Eastman, N. J.: Personal communication.

In their published paper the Philadelphia workers have suggested, on the basis of their results in early and latent syphilis combined together, "that the pregnant syphilitic women with *early*[8] syphilis, treated with penicillin, may be expected to remain seropositive even though the treatment is apparently effective, for as long as six months to one year. . . . The serologic response here noted is considerably slower than that recorded . . . for early syphilis as a whole." This conclusion seems unjustified, because of lack of separation of their published material as between early and latent syphilis. It is already known that the serologic response to penicillin of patients with long-standing syphilitic infection (i. e. of two years' duration or longer) is considerably less prompt and less in proportion of numbers than in manifest early infectious (primary or secondary) syphilis.

In our material, which consists entirely of patients with early syphilis, we have seen nothing to suggest that pregnancy exerts any effect in slowing up serologic response, since our pregnant patients have reverted toward negative at the same rate as nonpregnant females or males.

TABLE 3.—*Status of Infants Born of Penicillin Treated Mothers*
(As of Sept. 10, 1945)

Author	Number of Mothers So Far Delivered	Number of Infants	Infants Born Alive Apparently Normal at Birth	Infants Developing Syphilis	Infants Seropositive at Birth, Reverting Spontaneously to Negative During Specified Month of Life			Duration of Follow-Up of Infants Apparently Normal at Birth, Months				Follow-Up of Infants Apparently Normal at Birth			Death of Infants Apparently Normal at Birth
					1st	2d	3d	2	2-6	6-12	12+	P. E.	X-Ray	Serologic	
Ingraham and others	26	27[1]	27	1[2]	7	2	..	3	11	6	7	26 normal	26 normal	26 normal	1 at 7 mo. of age from acute febrile illness, undetermined cause, autopsy negative for syphilis
Goodwin and Moore	31	33[3]	33	0	8	..	1	8	18	7	..	33 normal	All[4] normal	33 normal	1 at 19 weeks, acute nutritional disturbance and sickle cell anemia; STS negative at time; no autopsy
Total............	57	60	60	1	15	2	1	11	29	13	7	59 normal	All[4] normal	59 normal	2

1. One mother had two pregnancies during the second of which no treatment was given.
2. Mother given 1.2 million units for secondary syphilis at 5th month of pregnancy; clinical relapse in mother at 9th month of pregnancy; infant infected.
3. Two mothers had two pregnancies during the second of which no treatment was given.
4. Roentgenograms done routinely in Baltimore (see text) on only 17 of 33 infants because of shortage of x-ray film, but all of them normal.

OUTCOME OF PENICILLIN TREATMENT IN THE PREVENTION OF CONGENITAL SYPHILIS

In this respect we are able to confirm completely the spectacular results reported by the Philadelphia group (table 3). Of the 26 Philadelphia mothers with early syphilis (included herewith through Ingraham's courtesy), all had delivered as of Sept. 10, 1945. One of these 26 women has had two pregnancies, during the first of which penicillin was given, and during the second no treatment of any kind. All of the 27 infants born of these 26 mothers were alive and apparently normal at birth. One of them, born of the mother who was found to have infectious relapse at the time of delivery, developed clinical, serologic and x-ray evidence of syphilis, beginning some seven weeks after birth. The other 26 infants are still normal.

All of the 31 mothers in our own series have now been delivered. Two of them have been pregnant twice, penicillin being administered in each case during the first pregnancy, and no treatment during the second. Thirty-three infants are therefore represented. All of these were born alive and apparently normal at birth. Not one of the infants has developed any clinical, serologic or roentgenographic evidence of congenital syphilis.

Of the combined 60 infants in the Philadelphia and Baltimore series (excluding the 1 Philadelphia infant who developed congenital syphilis) 11 have been followed for less than two months, 29 for from two to six months, 13 for from six to twelve months and 7 for more than twelve months. The Baltimore infants have been followed in the same manner as those of the Philadelphia series, with frequently repeated quantitatively titered blood serologic tests, roentgenograms of the long bones (see footnote 4 in table 3) and physical examinations.

We would modify the probable outcome in the infants of penicillin treated syphilitic mothers from the published opinion expressed by Ingraham and his group, as follows: We believe that in all of the infants followed for six months or more the diagnosis normal (or nonsyphilitic) is definitely established. In infants followed for from two to six months it is highly improbable that the diagnosis must be later modified. We agree, of course, that no final decision is possible in infants followed less than two months.

In this connection attention is particularly directed to the fact that in the combined Philadelphia and Baltimore series 19 infants apparently normal at birth had at the time or within the first week of life positive blood serologic tests in cord or venous blood. In all of these infants the mothers were seropositive at the time of delivery. One, the Philadelphia child just referred to, has developed congenital syphilis. The other 18 (table 3) have all become spontaneously seronegative. In 15 of these 18 permanent seronegativity was achieved within the first month of life, in 2 within the second month and in 1 within the third month (on the seventy-third day). These data support the opinion that following penicillin treatment of the infected syphilitic mother a three months observation period of the child, with sustained seronegativity and absence of clinical or roentgenologic evidence of syphilis, represents at least 95 per cent certainty that the child has not been infected.

---

[8] Italics ours.

DEATH OF INFANTS APPARENTLY NORMAL AT BIRTH

Of the 60 children born alive in the combined Baltimore and Philadelphia series, 2 have subsequently died at nineteen weeks and seven months respectively. Neither of these deaths could be attributed to syphilis.

COMMENT

Comparison of Penicillin Results in the Prevention of Prenatal Syphilis with Those Obtainable from Metal Chemotherapy.—In most, if not all, of the older literature dealing with the prevention of prenatal syphilis by treatment of the mother with "standard" prolonged arsenic-bismuth-mercury, there is a curious hiatus. Most of the reporters of large series of cases (including the several publications of the University of Pennsylvania group, mostly by Ingraham, and including also the extensive study of McKelvey and Turner [9] from our own clinic) have fallen into the error of disregarding the stage of clinical manifestations and the duration of infection in the mother. Results have been based on a specified number of mothers "with syphilis" without regard to the varying prognosis as to the child in the absence of maternal treatment, depending on these important factors.

TABLE 4.—*Outcome of Pregnancy in Syphilitic Women Arranged by Duration of Infection in the Mother*

(Modified from Paley [10])

Amount of Treatment Given Mother During Pregnancy, Doses of Neoarsphenamine	Duration of Mother's Infection *					
	Less Than 2 Years †		2-5 Years		More Than 5 Years	
	Number of Mothers	"Syphilitic Tragedies" in Infants, %				
4 ‡	47	76.6	58	36.2	109	38.5
4-7	49	48.9	57	21.0	104	10.5
8+	42	23.8	58	18.9	93	6.4

* See text of the present paper regarding accuracy of these time intervals.

† This group of women, infected less than two years, presumably contains both those with manifest lesions of early syphilis and others with asymptomatic latent syphilis.

‡ This treatment group, of "less than four doses of neoarsphenamine," presumably includes some patients (number not stated) who received no treatment during pregnancy.

TABLE 5.—*Probability of Syphilitic vs. Normal Infants After Varying Amounts of Treatment in Mothers with Early and Late (Usually Latent) Syphilis*

(Recalculated from Turner and McKelvey [9])

	Early Syphilis in Mother (71 Cases)		Late (Usually Latent) Syphilis in Mother (579 Cases)	
Treatment (in Terms of Gm. of Arsphenamine)	Infant Almost Certainly Normal, %	Infant Almost Certainly Syphilitic, %	Infant Almost Certainly Normal, %	Infant Almost Certainly Syphilitic, %
None	5	95	35	65
<2 Gm.	50	50	75	25
2-3 Gm.	70	30	90	10
3+ Gm.	95	5	98	2

To our knowledge Paley [10] is the only reporter of a large series of cases who may be excepted from these statements. This worker studied the outcome of pregnancy in 617 syphilitic women whom he subdivided into three groups on the basis of duration of infection in the mother, i. e. less than two years, two to five years, more than five years. He too omits any consideration of clinical manifestations in the mothers, and he does not provide information as to how he dated the infection in them. To determine accurately the duration of syphilitic infection in pregnant women is usually an impossible task, since most of them have no history of early lesions. It can be done only roughly and on the basis of the collateral evidence of age of the mother, the duration of her sexual activity and, in some cases, on data obtained from the father. Nevertheless, it is entirely probable that in Paley's group of women "infected less than two years" are included all those in his series with manifest lesions of early syphilis. Paley classifies the outcome in the infant in two groups, normal and "syphilitic tragedies." In the latter category he includes abortion, stillbirth and living children with syphilis. Subject to the comments made and to the accuracy of diagnosis of infantile congenital syphilis in 1937 (the date of his report), his data, summarized in table 4, indicated clearly the extreme hazard to the infant posed by recently acquired syphilis in the mother.

In order to document further the point that the outlook for the infant is worse if the mother has manifest early syphilis during pregnancy than in the later years of maternal infection, it is fortunate that the original work sheets of McKelvey and Turner [9] are still available. We have examined these records and have recalculated the infantile results on the basis in question. In the original series of McKelvey and Turner there were 650 syphilitic mothers to whom antisyphilitic treatment was administered for the first time during pregnancy. Seventy-one of these women had demonstrable early (primary or secondary) syphilis at the time; the remaining 579 were in later stages of the disease (usually latent). Included among these 579 are an undeterminable number with symptomless early infections; but this fact only lends greater significance to observable differences in the outcome in the infants of the two maternal groups.

During the period of the McKelvey-Turner study arsenical treatment administered to the mother was almost exclusively arsphenamine at weekly intervals in an average single dose of 0.3 Gm. The amount of treatment given may therefore be conveniently expressed in grams of this drug (i. e. 1 Gm. equals approximately three injections, 4 to 6 Gm. equals twelve to twenty injections, and so on). When more than 2 Gm. (six injections) of arsphenamine was given, a compound of heavy metal (mercury or bismuth) was usually employed as well. The total amount of arsphenamine given is a rough index to the duration of pregnancy at the start of treatment; i. e., the earlier treatment was begun, the more treatment the mother received before delivery, and vice versa. The same considerations as to treatment also apply to Paley's material.

Having these points in mind, the data of McKelvey and Turner have been recalculated and the results shown in percentage terms in table 5. The terms "almost certainly" normal or "syphilitic" respectively, as applied to the infant, have been purposely utilized because in some infants the evidence was presumptive rather than absolute and because the criteria of diagnosis of infantile congenital syphilis have undergone considerable modification since the publication of that paper (and of Paley's also). Nevertheless the figures presented are believed to be substantially accurate. No matter what amount of treatment was given to the mother, the results in the infant were substantially worse when the mother had early syphilis during pregnancy than when she had late or latent syphilis. In untreated early syphilis of the mother there was practically no chance of a normal infant unless the maternal infection had occurred within the last few days or weeks of pregnancy. In maternal latent syphilis (usually of several years' duration), on the other hand, 35 per cent of babies were normal and nonsyphilitic even in the absence of maternal treatment. These data are confirmatory of those of Paley but even more striking.

---

[9] McKelvey, J. H., and Turner, T. B.: Syphilis and Pregnancy: Analysis of Outcome of Treatment in Relation to Treatment in 943 Cases, J. A. M. A. **102**: 503 (Feb. 17) 1934.

[10] Paley, S. S.: Syphilis in Pregnancy, N. Y. State J. Med. **37**: 555 (March 15) 1937.

These facts are justification for a judgment of penicillin based on its effects in early maternal infections.

It is also notable that with the older system of administering metal chemotherapy to the mother at weekly intervals (even with oxophenarsine hydrochloride twice or three times weekly, we think) during the available time (i. e., between the dates of diagnosis and delivery), the best results in the fetus are not obtained unless treatment is started early in pregnancy, before the fifth month, and continued throughout its course.

About 150 pregnant women with early syphilis have been reported in the literature as treated with intensive arsenotherapy (usually about 1,200 mg. of oxophenarsine hydrochloride by intravenous drip or multiple syringe injection in five to ten days). The majority of these are contained in the papers by Sadusk and Shaffer,[11] Rattner,[12] Speiser and his associates [13] and Neilson and his group.[14] It is impossible to determine accurately from the published statements the outcome in the infants of these women, but the best possible approximation is furnished in table 6, where it is indicated that about 15 per cent of the babies had syphilis in spite of this treatment.

TABLE 6.—*Probability of Syphilitic vs. Normal Infants After Intensive Arsenotherapy of Early Syphilis in the Mother During Pregnancy*

	Infants	
Cases Treated	Syphilis (%)	Normal (%)
150 (approximately)...............................	15	85

Tables 4, 5 and 6 should be read in comparison with the penicillin results presented in table 3. Penicillin is incomparably superior to metal chemotherapy, no matter how administered, in the prevention of prenatal syphilis. After penicillin treatment of 57 mothers with early syphilis there were no dead infants and only 1 living infant with congenital syphilis among 60 infants born, a failure rate of 1.6 per cent; and this one failure might have been prevented by appropriate penicillin retreatment of the mother. With penicillin the results are equally good no matter what the duration of pregnancy at the time of treatment. This contrasts with a failure rate of 5 to 50 or more per cent from metal chemotherapy, depending on the time in pregnancy of institution of such treatment and the amount administered.

The Results of Penicillin Treatment of Mothers with Latent (or Late) Syphilis.—Ingraham and his associates include in their paper the outcome of treatment of 23 patients with latent (19 early—less than four years' duration; 3 late—more than four years' duration) and 1 with congenital syphilis. Among these women were two abortions, one at the fourth, the other at the seventh month of pregnancy. There is no statement provided in the paper as to necropsy findings in either fetus.[15] The 21 children were born alive and all were apparently normal with no examples of congenital syphilis. In view of the data presented in tables 4 and 5 this is also an excellent result, though hardly as impressive as in early maternal syphilis.

RECOMMENDATIONS

The data so far presented should be considered in conjunction with the known dangers of arsenic and bismuth therapy, the known nearly complete lack of toxicity of penicillin for the mother and the compression of penicillin treatment within a minimum time period of a few days.

In view of these facts, we are prepared to recommend that, for the purpose of prevention of prenatal syphilis, metal chemotherapy for the syphilitic mother whether with early or late (including latent) syphilis be abandoned and that penicillin be adopted universally in its stead.

Since therapy for the fetus should be planned in conjunction with that for the mother herself, and since definitive information as to the optimum method of use of penicillin in early or late acquired syphilis of adults is not yet available, it is possible to recommend treatment plans at present only as preliminary information permits. Certain minimum requirements should be met:

1. The total dose of penicillin should be not less than 2.4 million units administered intramuscularly in aqueous or saline solution at intervals of not less than two nor more than three hours night and day.

2. The total duration of treatment should be not less than seven and one-half days.

3. For the present, and until definitive information is available from research centers, absorption-delaying methods of use of penicillin (i. e. as in peanut oil-beeswax) should not be used.

4. Following completion of penicillin treatment, the mother must be followed clinically and with quantitatively titered serologic tests at least as often as once a month until delivery (and preferably for the first year after treatment) and at appropriate intervals thereafter.

5. Retreatment with penicillin should be given during pregnancy to the mother if (*a*) there is evidence of clinical or serologic relapse or (*b*) the original maternal serologic titer does not significantly decline within three months after treatment.

6. The infant must be followed after birth for a minimum period of three months by means of (*a*) frequently repeated physical inspections, (*b*) quantitatively titered blood serologic tests, preferably every two weeks, and (*c*) roentgenograms of the long bones taken preferably at the first and sixth weeks of life.

7. There is no satisfactory evidence that abortion, actual or threatened, is more frequent during penicillin treatment of the mother than during other forms of antisyphilitic treatment, or indeed more frequent than the expected incidence of spontaneous abortion in normal women. Unless and until such evidence is forthcoming, speculation is useless as to whether the phenomenon is due to therapeutic shock or to the direct oxytocic action of penicillin.

14. Neilson, A. W.; Blaney, L. G.; Stephens, L. J., and Maxwell, R. W.: Intensive Chemotherapy of Early Syphilis, Am. J Syph., Gonor. & Ven. Dis. **28**: 553 (Sept.) 1944.

15. The autopsy of the child stillborn at the seventh month showed no definite evidence of syphilis. Grossly, syphilitic epiphysitis appeared probably to be present in the long bones, but this could not be confirmed histologically because of autolysis. There are no available pathologic data on the fetus aborted at the fourth month (Ingraham[4]).

On the basis of the data presented in this paper, we see no reason for unusual caution in initiating the penicillin treatment of syphilitic pregnant women.

8. It is not yet determined whether a woman with early syphilis, treated with penicillin while nonpregnant or during an earlier pregnancy, may be permitted to go through a subsequent pregnancy without treatment. Although 3 women in the present series have delivered normal children in a second pregnancy in which no treatment was given, further experience must accumulate before the point can be decided. Pending further information, a pregnant syphilitic woman previously treated with penicillin, and whether or not this earlier treatment was apparently successful as to the mother's infection, should be retreated with penicillin in each succeeding pregnancy.

SUMMARY

1. Fifty-seven pregnant women with early syphilis have been treated with penicillin in two university clinics. Sixty infants have been born to these women, all of whom were born alive; only 1 has developed clinical or laboratory evidence of congenital syphilis. In this 1 case, syphilis in the child might possibly have been prevented. The remaining 59 infants are all apparently normal, and 42 of these have been followed for a long enough time after birth to make practically certain of the diagnosis of "no syphilis."
2. These results in the prevention of prenatal syphilis are superior to any heretofore attainable with any method of treatment.
3. There is no satisfactory evidence that penicillin is directly or indirectly responsible for abortion.
4. It is recommended that in syphilitic pregnant women penicillin be used routinely for the prevention of prenatal syphilis, other methods of treatment being abandoned.

PENICILLIN TREATMENT OF THE SYPHILITIC INFANT

This paper is a supplement to our observations on this same subject recorded about a year ago.[1] Our increasing experience still leads us to feel that sodium penicillin given by intramuscular injection is a satisfactory treatment for infantile congenital syphilis. Considerable progress has been made toward arriving at a satisfactory regimen for the infant infected with syphilis. There is no denying the fact, however, that this problem has seemed considerably more complex to work out than has been the treatment of early syphilis in the adult, with penicillin, largely because of the relative severity of the disease frequently encountered in the newborn in contradistinction to that found in the adult and because of the theoretical dangers inherent in the injudicious use of a rapidly spirillicidal drug under such circumstances. Even though this study is still in progress and much is yet to be learned in the application of penicillin treatment to the syphilitic infant, yet, as the material is accumulating, a conservative appraisal of our existing knowledge seems worth while.

MATERIAL

Thus far we have treated with penicillin 26 infants with early congenital syphilis. The average age of these infants at the time of commencement of therapy has been 3.6 months. Fourteen of the babies have been less than 3 months of age, 7 between 3 and 6 months, 2 between 6 months and 1 year and 3 more than 1 year. Twenty-three of the infants were Negroes, 3 were white, 11 were boys and 15 were girls.[2] None of them had previous treatment for syphilis. All of the infants had clinical evidence of their disease; in many instances dark field examination of surface lesions revealed Treponema pallidum; in almost every case roentgenographic evidence of osteochondritis and periostitis was demonstrable. Latent (symptomless) syphilis in infants was excluded from the study in order better to measure the response to treament by a variety of methods.

At the time of compilation of this material, 21 of the 26 infants are still living. These 21 infants have been followed for an average of 7.6 months after being given penicillin, maximum fifteen months. Four of the infants have been followed for more than one year, 10 for periods of six months to one year and 7 for periods of less than six months after penicillin.

TYPE OF TREATMENT GIVEN AND RESULTS OF THERAPY

It was the purpose of this study to determine what penicillin as such would accomplish in the cure of this disease rather than to find the ideal dosage. The latter will have to be worked out in larger series of cases observed over longer periods. At first we used the approximate equivalent dosage of 2.4 million units for a 150 pound (68 Kg.) adult or 16,000 units total dosage per pound of body weight. Later this dosage was considerably increased, so that of the total number of infants 11 received dosages of sodium penicillin roughly in amount of 16,000 units per pound of body weight; 3 received dosages significantly lower than this; 9 received single courses of therapy with dosages significantly greater than this, and 3 were retreated because of failure of clinical response.

Of the infants who reacted favorably to treatment the initial clinical response has been uniformly good. Symptoms and signs have improved or disappeared; roentgenographic findings, initially abnormal, have gradually regressed over periods of three to six months. The response of the blood serologic test in the group as a whole may be briefly summarized as follows:

Eleven of the 21 living infants have become seronegative in the period of observation. In 3 additional cases the blood serologic titer has regressed from relatively high values to less than 1 unit of syphilis reagin. In those cases which have responded the initial sustained fall in titer was noted on an average eighty-eight days after penicillin (17 cases). The average length of time to obtain sustained seronegativity (11 cases) was one hundred and sixty-eight days after penicillin, with a maximum of two hundred and fifty-seven days and a minimum of seventy-eight days before the first negative test was noted. This serologic response is roughly comparable to that described for the syphilitic

pregnant woman by the University of Pennsylvania group in another paper to be published and materially slower than that obtained in adults.[3] There is some definite reason to believe that this slow response, with occasional relapse and failure to respond at all in some instances, is the result of too low total dosage of the drug or of too short a course of penicillin, as the summary in the accompanying table indicates.

One half of the infants treated with dosages comparable to 2.4 million units in the adult were seropositive at the end of six months, but only 1 in 7 cases remained positive when larger dosage was used. It was the conclusion reached in the National Venereal Disease Control Conference in St. Louis in November 1944 that the dosages employed in infantile syphilis up to that time (16,000 to 32,000 Oxford unit total dosage per kilogram of body weight) were too low.[4] Our experience since that time would seem to indicate that very much larger dosage is desirable. The child (285) in the present series who became seronegative in the shortest time (seventy-eight days), a 5 week old Negro boy with symptoms of his infection and 128 units of syphilis reagin according to quantitative titered tests at the commencement of therapy, received a total dosage of 74,000 Oxford units per pound of body weight over a period of fifteen days. This is roughly four times the dosage recommended for trial at the St. Louis conference and the approximate equivalent of 11.1 million units total dose for the 150 pound adult. It will be recalled that infantile congenital syphilis is a much more severe and extensive infection than is encountered in early infection in the adult and that, provided safe systems of administration can be found, the anticipated effective dosage would be much greater in the congenitally infected infant than in acquired syphilis.

Since the cases summarized in table 2 of our previous report [1] we have had three additional deaths, bringing our total to five. None of these deaths could be attributed to penicillin. Two of them and possibly the third could be attributed to intercurrent infection in an infant in a debilitated state as a result of a severe systemic disease (syphilis).

Patient 286 was a 5 pound 10 ounce (2,550 Gm.) 4 week old Negro girl in almost moribund state at the time she was admitted to the hospital. There were 32 units of syphilis reagin in the blood to the quantitative titered Kline test and extensive osteochondritis and periostitis of the syphilitic type shown by the roentgenogram. The infant was given all possible supportive treatment and started on small doses of penicillin intramuscularly. She died after twelve hours, having received five injections of 350 Oxford units each of sodium penicillin. Autopsy revealed the immediate cause of death as an extensive bronchopneumonia. It would seem that in this infant penicillin probably had no part either favorable or unfavorable in the outcome. It will be recalled that congenital syphilis is often a fatal disease in utero and during the first few weeks of life. It is expecting too much for penicillin or any known mode of therapy to be successful in such a case. A trial of the most effective type of treatment is certainly indicated, however.

Patient 299 died of pneumonia three months after the completion of penicillin therapy. In this instance we were unable to obtain an autopsy. This infant with clinically manifest infantile congenital syphilis was a Negro boy 6 weeks old at the time of commencing treatment, Oct. 25, 1944. He received a total dosage of 61,540 Oxford units per pound of body weight in twelve days. His clinical response was good and his blood serologic test, which had been as high as 128 Kline titered units of reagin, dropped to 2 units by Jan. 17, 1945. The initially positive roentgenogram of the long bones showed healing. Infection with pneumonia followed immediately thereafter, and death occurred on January 30. There was nothing to indicate that death resulted either from syphilis or from its treament. There is every possibility, however, that syphilis was indirectly the cause of death, the initial debilitation of the child, from which he had never completely recovered, predisposing to intercurrent infection.

Patient 397 was a 3 month old Negro boy with bronchopneumonia superimposed on a severely debilitated state from congenital syphilis when he was treated with a total dosage of 224,664 Oxford units of sodium penicillin over a period of eleven days commencing Dec. 1, 1944. In spite of this treatment and expert general pediatric care at the Children's Hospital, the course was steadily downhill, and the infant finally died on December 28. Staphylococcus aureus had been cultured from the blood stream at the time of admission. There was an otitis media. Roentgenograms showed extensive syphilitic osteochondritis and periostitis, which was improving at the time of death. Blood serologic tests for syphilis were strongly positive throughout the period of observation. No autopsy was performed. This represents another case in which penicillin was unsuccessful in combating the complications and debilitation accompanying advanced infantile congenital syphilis.

Relationship of Serologic Response to Total Dosage in Infants with Congenital Syphilis Treated with Penicillin and Followed for at Least Six Months After the Completion of Therapy

Total Dosage of Penicillin	Serologic Response in Period of Observation	
	Positive	Negative
1. Less than 20,000 units per pound.....	4 cases	4 cases
2. More than 20,000 units per pound....	1 case	6 cases

Forty per cent of the infants treated with penicillin developed symptoms of severe gastrointestinal disturbance in addition to temperature reaction. This consisted in abdominal distention, loss of appetite, varying degrees of diarrhea and in some instances vomiting. Gastrointestinal disturbances as a result of the toxemia of congenital syphilis are well known.[5] In some of the infants these symptoms were manifest at the time of admission but almost uniformly were much accentuated within forty-eight to seventy-two hours after the commencement of treatment. They had a tendency to regress and to disappear as the treatment was completed.

There has been much discussion since the publication of our last report among the pediatricians and the syphilologists of the university penicillin group concerning the importance and significance of the Herxheimer reaction to penicillin. Recently 7 infants whose physical condition at the commencement of therapy was good have been given full dosage from the start instead of the previously recommended reduced dosage. All of these have done well. The question of careful judgment arises therefore, largely with regard to the infant who is already in a debilitated state when he is brought to medical care. In such instances expert pediatric attention is of paramount importance.[5a]

SUMMARY OF THE PRESENT STATUS OF OUR KNOWLEDGE IN THE TREATMENT OF THE SYPHILITIC INFANT WITH PENICILLIN

The appropriate total dosage and time dose relationship in the treatment of infantile congenital syphilis has still not been determined, but there is little doubt that penicillin exercises a favorable influence in the treatment of early congenital syphilis. It would seem that, in general, the dosages of penicillin used for infantile congenital syphilis have been too low and that they should be greatly increased, possibly considerably in excess of 20,000 Oxford units of sodium penicillin per pound of body weight, total dosage. There is also the impression with the material at present available that the treatment course should be prolonged to ten or fifteen days rather than limited to seven or eight days as in the past. This is in line with the recently published work of McDermott and his co-workers,[6] which indicates that the important factor in the treatment of syphilis with penicillin is not high dosage but prolonged action at low concentration. It is also apparently unnecessary to reduce the initial dosage of penicillin. In greatly debilitated children treatment should be approached with considerable caution and with maximum supportive general pediatric care. With sodium penicillin the drug should be administered intramuscularly every three hours for the duration of the treatment.

Of those infants in the present series which have been followed for periods of longer than six months after treatment with penicillin 10 (71 per cent) have remained clinically normal and are seronegative; 4 are clinically normal but have remained seropositive. This percentage success does not nearly approach that which is being obtained thus far in early acquired syphilis in the adult and serves only further to emphasize the fact that much study is still required. The cases which have remained seropositive or which have relapsed have been retreated with dosages of penicillin in excess of 20,000 Oxford units per pound of body weight. We have not used other modes of chemotherapy for syphilis in conjunction with penicillin.

CONCLUSIONS

Since this study is still in progress, any conclusions which may at present be drawn must be subject to modification as additional information is collected. The following statement, however, does represent our present working knowledge in the field of penicillin treatment of the syphilitic infant:

1. Initial attempts at the treatment of infantile syphilis with penicillin have borrowed their dosage and length of therapy from experience with the disease in the adult and have given a degree of success of about 70 per cent. A higher percentage of favorable results is to be hoped for as better time dose relationships are worked out.

2. Some evidence is presented to indicate that the total dosage of sodium penicillin by intramuscular injection should be greatly increased for infants. It is also suggested that prolongation of treatment up to two weeks is desirable.

3. The range of total dosage employed for infants treated in this series has been from 11,000 Oxford units per pound to 74,000 Oxford units per pound of body weight given over a period of from seven to fifteen days. The larger total doses with the longer periods of treatment have given the better results.

[5a] The pediatric aspects of management will be discussed in more detail in a subsequent communication.

[6] McDermott, W.; Benoit, M., and Du Bois, R.: Time Dose Relationships of Penicillin Therapy: III. Regimens Used in Early Syphilis, Am. J. Syph., Gonor. & Ven. Dis. 29: 345 (May) 1945.

TREATMENT OF EARLY SYPHILIS WITH PENICILLIN

ARTHUR G. SCHOCH, M.D.,
and
LEE J. ALEXANDER, M.D.
Dallas, Texas

Penicillin, properly administered, will cure the majority of patients with primary and secondary syphilis! We base this statement on personal observation of over 900 patients with early syphilis and on intimate knowledge of results obtained by other investigators.

Even the most skeptical now are willing to admit the effectiveness of the sodium salts of penicillin injected intramuscularly, usually at a three hour interval day and night, over a period of from seven to ten days. Adequate dosage will produce a percentage of cures in cases of early syphilis (primary and secondary) as good and probably better than chemotherapy.

We do not wish to leave the impression that an optimum dosage schedule has been developed. Investigators concerned with this particular subject are still striving toward that goal.

However, it is reasonable to suppose that sometime during the next five years such an optimal schedule of treatment for early syphilis will be found. It may be 5 million units of penicillin in seven and one-half days; it may be a combination of penicillin with arsenic and/or bismuth. It may be delayed absorption penicillin (our immediate problem) suspended in peanut oil-beeswax mixture, or it may be the administration of the penicillin orally. Nevertheless it probably will be penicillin, unless a new antibiotic makes its appearance that is more effective against the spirochete of syphilis than the penicillin of today.

Certainly the curability of syphilis depends on (1) total dosage, (2) injection interval, (3) duration of treatment days and (4) the addition of other antisyphilitic drugs.

A discussion of oral penicillin in the treatment of syphilis is too experimental to deserve consideration in this paper.

Let us therefore look at what is known of the effect of sodium penicillin injected intramuscularly, using a modification (20,000 units of penicillin every three hours for seven and one-half days, total 1.2 million units) of Mahoney's original schedule (25,000 units every four hours for eight days, total 1.2 million units) at one extreme and, at the other extreme, the newer penicillin preparations under investigation at present, namely delayed absorption preparations.

Paper in a symposium on "The Penicillin Therapy of Syphilis" published under the auspices of the Section on Dermatology and Syphilology.

From the Department of Dermatology and Syphilology, Southwestern Medical College, and the Dallas Syphilis and Venereal Disease Clinic, Parkland Hospital.

The work described in this paper was done under a contract, recommended by the Committee on Medical Research, between the Office of Scientific Research and Development and the Southwestern Medical Foundation.

We know now that a total dose of 300,000 units in seven and one-half days is frankly inadequate; likewise, a total dose of 600,000 units. Although probably effective, 1.2 million units still leaves an appreciable number of failures; therefore we feel that one is justified in using 2.4 million units of penicillin as the dosage of choice. This total dosage was adopted by the Army and Navy. (All schedules utilize intramuscular injections every three hours for seven and one-half days.)

We have used injection intervals of three hours, four hours, six hours and twelve hours. All except the three hour interval proved inadequate.

With regard to the time required in the treatment of early syphilis, we believe that, with a given dosage, cutting the time in half from seven and one-half days to a little under four days is inadequate therapy. Little is known about schedules requiring fifteen days instead of seven and one-half days. We predict, however, that a fifteen day schedule probably will not be significantly superior to a seven and one-half day schedule, the individual dose remaining constant. From a practical standpoint it seems illogical to treat patients fifteen days in order to gain a slight advantage. Why not be satisfied with a schedule of treatment that yields approximately 90 per cent "cures," carefully follow these patients through the critical period of relapse and reinfection, namely the first twelve months following treatment, and individualize the treatment of the failure group?

We believe, therefore, that the use of 2.4 million units of penicillin in seven and one-half days (40,000 units intramuscularly every three hours) is definitely justified but question whether doubling either the total dose and/or the total time is advisable.

Are we, in addition, justified in adding a chemotherapeutic agent to a course of penicillin, such as oxophenarsine hydrochloride, bismuth or both? We think the answer is definitely "yes."

Throughout the years most patients with early syphilis have been more successfully treated when more than one drug was utilized. Recent experience has indicated that the addition of oxophenarsine hydrochloride or bismuth salicylate to a course of penicillin probably cures more patients with early syphilis than if that dose of penicillin had been used alone.

Evan Thomas at Bellevue Hospital in New York treated several hundred patients with 1.2 million units of penicillin and, in addition, gave 40 mg. of oxophenarsine hydrochloride intravenously daily for eight consecutive days during the time the penicillin was administered. We have treated several hundred patients with the same penicillin schedule with the addition of five intramuscular injections of bismuth salicylate, giving 0.2 Gm. of bismuth salicylate in oil the first, third, fifth, seventh and ninth days.

These two systems of treatment are comparable but, naturally, are too young to evaluate. However, certain impressions and certain preliminary statistical observations are definite to him and to us. Even in a limited period of observation, namely a little more than a year, the percentage of failures in Thomas's group and in ours is perceptibly less than when patients were treated with penicillin alone, with comparable periods of follow-up observation.

It might be argued that the addition of oxophenarsine hydrochloride in Thomas's series, and bismuth in our series, merely delayed or postponed the appearance of failures in the form of relapse or reinfection. It probably would have no influence on the incidence of reinfection, but we must freely admit that a system of treatment which combines penicillin with arsenic, or penicillin with bismuth, might conceivably delay by a number of months the incidence of relapse lesions in the given patient or in any group of patients. Hypothetically, this should be more true of patients treated with combined penicillin and bismuth than with patients treated with penicillin and arsenic. Preliminary observations, however, are most encouraging. Therefore it would seem wise to add a reasonable amount of oxophenarsine hydrochloride, bismuth salicylate in oil or both to any penicillin regimen for the treatment of early syphilis.

Which, then, should we add to the "standard" Army and Navy treatment schedule of 2.4 million units of penicillin given in a seven and one-half day period, oxophenarsine hydrochloride or bismuth or both?

At present, from a practical standpoint, the answer seems obvious. Add the safest form of chemotherapy, bismuth, and exclude the most dangerous, arsenic.

We shall not consider the experimental work now in progress combining the use of intramuscular penicillin with fever therapy. Even if this combination were provocative of an optimum "cure rate," it could not be recommended for routine mass treatment of early syphilis, for obvious reasons.

The much argued question of what constitutes relapse and what constitutes reinfection has been clearly and concisely summarized in an editorial by Moore in the July 1945 issue of the *American Journal of Syphilis, Gonorrhea and Venereal Diseases.* Since the advent of all rapid methods of treatment of syphilis, beginning with the five day intravenous drip until the present day, syphilologic conservatism has relegated reinfection into the category of relapse in evaluating all newer methods of treatment. The present coordinated study being carried out under the direction of the Penicillin Panel of the Subcommittee on Venereal Diseases of the Committee on Medical Research is no exception. It has been admitted by some (J. E. M.) that reinfection occurs now many times more frequently than formerly and that systems of treatment that are completed in a week or ten days result in reinfection between husband and wife by virtue of the nature of the disease and aptly labeled "ping pong syphilis" by William E. Graham. If reinfections occur at an appreciable rate, then it seems perfectly obvious that the irreducible minimum of failures is slightly greater than the reinfection rate.

We have observed reinfections in numerous cases of conjugal syphilis. In several such instances by treating both the infected spouse and the exposed partner at the same time we have apparently prevented further reinfection in these couples.

The uniform response of chemotherapeutic treatment resistant syphilis to penicillin, as recently reported by Russell Nelson and others; the conspicuousness, by its absence, of penicillin resistant primary and secondary syphilis in many thousands of patients treated with penicillin; the lack of experimental or clinical evidence of a penicillin resistant strain of Treponema pallidum are, to say the least, unusual for a syphilotherapeutic remedy.

SUMMARY

The foregoing observations bring us squarely before the all important question In view of what is known today, how should early syphilis (primary and secondary) be treated?

1. The minimum dosage should be at least 2.4 million units of penicillin; the total time required should be a minimum of *seven and one-half days; the interval*

between individual intramuscular injections should be a maximum of three hours, day and night.

2. In addition to penicillin treatment the patients should receive either oxophenarsine hydrochloride intravenously, 40 mg. daily for 8 doses, or five injections, 0.2 Gm. each, of bismuth salicylate in oil on alternate days, or both. We ourselves prefer the addition of bismuth alone to the penicillin treatment schedule in order to obviate completely the possibility of arsenic reactions inevitable in a large series of cases when oxophenarsine hydrochloride is used even in small amounts.

3. A regular and thorough follow-up of all treated patients for a minimum of five years is essential to proper management. The follow-up must include adequate quantitative serologic determinations and adequate spinal fluid examinations.

4. The management of the occasional penicillin failure should be individualized and expertly planned.

5. We strongly urge that intimate contacts of the patients be treated coincidentally with the treatment of the patient, to avoid reinfection.

PENICILLIN IN THE TREATMENT OF NEUROSYPHILIS

PAUL A. O'LEARY, M.D.
LOUIS A. BRUNSTING, M.D.
and
ORVILLE OCKULY, M.D.
Fellow in Dermatology and Syphilology, Mayo Foundation
Rochester, Minn.

Our experience with the clinical application of penicillin in the treatment of neurosyphilis is now in the early part of its third year. During this time certain impressions have been gathered which indicate the trend of the results of treatment. However, the period of observation is still too short to justify any attempt to make conclusive deductions as to the merit of penicillin in the treatment of neurosyphilitic patients. In fact it is well not to draw conclusions as to the success or failure of any method of treating neurosyphilis until a minimum of three years and preferably five years has elapsed since the treatment was started. Accordingly, this report is a brief summary of the observations on 100 patients who had neurosyphilis and who were treated by various systems in which penicillin was employed during the past two years.

The reports in the literature are at variance as to the value of penicillin in the treatment of neurosyphilis. Gammon and his associates[1] expressed the opinion that it was of value and noted especially the influence on the reactions of the cerebrospinal fluid. They expressed the belief that larger doses (4,800,000 units) than had been used might offer better results. Rose[2] reported that penicillin is an active therapeutic agent in cases of neurosyphilis but that further observation was necessary to determine its real value. Thrasher[3] reported that penicillin given by the Swift-Ellis technic produced clinical improvement in most of the cases, with serologic changes following later. Rose and his associates[4] also reported observation of a group of patients who had neurosyphilis and who were given penicillin with fever therapy. They could find no striking difference at this period of these patients from patients treated by the older methods. Neymann and his associates[5] expressed the opinion that the results following penicillin therapy among patients who had dementia paralytica were unsatisfactory. All of the reports appearing in the literature are thus far colored with varying degrees of conservatism, and all emphasize the fact that a longer period of treatment and observation is necessary before conclusive deductions can be made.

It is generally agreed, as originally observed by Barksdale and Thompson,[6] that meningeal neurosyphilis responds satisfactorily, both clinically and serologically, to penicillin therapy. In fact, the single outstanding effect of the remedy among our patients seems to be the reversal of the reactions of the cerebrospinal fluid, especially the reduction of the lymphocytic cell count; the higher the degree of pleocytosis at the time when treatment is started, the more rapid and striking is the reduction of the number of cells. The other factors in the reaction of the cerebrospinal fluid also decrease but in less degree in the following order of frequency: protein, colloidal gold curve and serologic reactions. In the majority of our cases, although the cell count, protein and gold curve reactions returned to within normal limits, the serologic reactions of the cerebrospinal fluid tended to remain persistently positive. The significance of this often inactive, but nonetheless positive, reaction warrants further observation before it is interpreted as indicative of an impending highly successful therapeutic effect. From the clinical standpoint the most pronounced therapeutic effect that we have observed has been a gain of weight following a course of penicillin. One patient who had tabes dorsalis gained 50 pounds (22.7 Kg.) in four months following treatment, while a gain of 20 to 30 pounds (9.1 to 13.6 Kg.) was fairly common in other cases. The average gain of weight of patients who had various types of neurosyphilis was 10 pounds (4.5 Kg.). A reduction of "leg pains" occurred in 15 per cent of the cases in which this complication of tabes dorsalis was present and a "general improvement," consisting of somatic changes for the better, was noted in about a third of the cases.

The other clinical manifestations, such as ataxia, crises (gastric and rectal), incontinence, irritability, nervousness, dysarthria and changed personality, were not helped when penicillin was given alone.

We have given penicillin by intramuscular, intravenous and intraspinal routes to patients who had neurosyphilis. We have administered it while the patients were undergoing, and after they had undergone, malarial therapy and hyperthermy. The dose has varied from 1,200,000 to 8,000,000 units in a period of seven to ten days. The periods of observation range from September 1943 to October 1945 and, of the 100 patients treated, follow-up data, which form the basis of this report, are available on 70.

In September 1943, when we first used penicillin in the treatment of syphilis following the suggestions of Mahoney, Arnold and Harris,[7] the drug was difficult to obtain because of its limited production. Accordingly, we gave it intravenously because it had been demonstrated by Herrell[8] that, when given by this route to patients who had infectious diseases, much smaller amounts of the drug could be given with equally satisfactory results. The intravenous administration of penicillin by the continuous drip method produced technical difficulties with complications such as phlebitis that made this mode of administration cumbersome. In comparing the patients treated two years ago by the intravenous technic with those who were treated by the intramuscular technic, the results are in favor of the former. The outstanding serologic result of the entire group of patients occurred in a young man who had early asymptomatic neurosyphilis and who was given 1,200,000 units of penicillin intravenously in seven days and three spinal drainages. The grade 3 type of spinal fluid noted when treatment was started became completely negative within six months thereafter. Similar but less conspicuous results were encountered in 3 other cases in which this procedure was employed; however, at this time, although the intravenous method of giving penicillin may show a slight superiority to the intramuscular technic, the complications and technical difficulties of the former procedure offset its slightly better results.

The attempt to recover penicillin in the cerebrospinal fluid following its intravenous or intramuscular injection was an interesting part of our early experience. If doses up to 100,000 units were given in twenty-four hours, we were able to recover penicillin in the cerebrospinal fluid in varying amounts, but it is now known that when large doses, such as several million units, are given intramuscularly in a period of twenty-four hours, it is possible to recover penicillin in the cerebrospinal fluid in correspondingly large amounts. Even though we were able to recover penicillin in the cerebrospinal fluid following administration of comparatively small doses, it was thought advisable to employ also spinal drainage and intraspinal therapy. Five patients were given 55,000 units intraspinally by means of the Swift-Ellis technic. As previously noted, the most complete and most rapid serologic reversals occurred in the cases in which spinal drainage or intraspinal therapy was used in conjunction with the intramuscular use of penicillin.

The next procedure that we employed in this appraisal program was the combined use of fever therapy and penicillin. As it was easy to demonstrate that penicillin was ineffectual against Plasmodium vivax, patients undergoing malarial therapy were given at first 1,200,000 units of penicillin intramuscularly during ten days of the fever course. The dose was eventually increased up to a total of 8,000,000 units given intramuscularly at the rate of 50,000 units every three hours. Fifty-six patients, of whom 19 were tabetic, 25 were paretic and 12 had asymptomatic neurosyphilis, received the combination of penicillin and fever therapy.

We find it difficult to distinguish the results of the combined use of penicillin and fever therapy from those of fever therapy alone. In other words, it seems that, when penicillin was given during or after the fever course, there was no appreciable improvement of the clinical or serologic changes over those who received only the fever treatment. Of the neurosyphilitic patients who had tabetic and paretic forms of the disease and who received penicillin alone, the clinical therapeutic effects were essentially negligible when compared with those for a similar group given malarial therapy. Accordingly, the addition of penicillin to a fever course either by malarial inoculation or by the fever cabinet has added but little to the betterment of the patients.

The clinical improvement that was noted by some patients following penicillin therapy was of a vague type, which can be summarized by the general statement of the patient "I feel better." On attempting to analyze this, it was not possible to elicit any constant changes in the group as a whole, although gain of weight and slight decrease of pains in the legs were the outstanding results. The crisp type of improvement that occurs following malarial therapy was not observed in the group who received only penicillin. Increasing the dose to 8,000,000 units did not increase the degree of improvement, nor has the administration of three courses of penicillin of 2,400,000 units each, given at two month intervals, been of additional help in this regard. We have been impressed with the fact that improvement following administration of penicillin comes within two or three months after treatment, while improvement following malarial therapy may not be fully manifested for two or three years thereafter. Of the patients who had a high cell count in their cerebrospinal fluids, clinical improvement did not parallel the serologic improvement. No benefit was noted from use of penicillin alone among patients who had gastric crises, incontinence or ataxia, although 1 patient who had diplopia was improved. One tabetic patient who had been serologically negative for fifteen years and had severe pains in the legs became disoriented toward the end of the course of penicillin and died three months later without regaining his mental equilibrium.

In cases of early dementia paralytica in which penicillin alone was given, no appreciable clinical improvement was noted. The irritability, nervousness and forgetfulness were not significantly altered. However, in cases in which malarial therapy and penicillin were administered, the results were comparable to those of the malarially treated group. Our experience was equally unimpressive among the institutionalized paretic patients who had the advanced forms of the disease.

Patients who had the meningovascular types of neurosyphilis and 2 patients who had amyotrophic lateral sclerosis and positive serologic reactions of the blood and cerebrospinal fluid derived no benefit from 2,400,000 units of penicillin alone.

We have already mentioned the serologic changes noted in these cases. The return of the cell count, protein and colloidal gold curve to within normal limits is observed constantly, but it is not accompanied in the majority of cases by a corresponding degree of clinical improvement. This divergence of the clinical and serologic results warrants further observation and study. Perhaps in three or four years it may permit of more favorable interpretation than we can make of it at this time.

The serologic reactions of the blood likewise show a tendency to reduction of both the complement fixation and the titer but, as noted in the studies of the cerebrospinal fluid, the reversals to negative or weak positive and the reduction of the titer are not paralleled by similar clinical improvement.

---

SUMMARY

The preliminary impressions gained in the past two years by treating 100 patients who had various types of neurosyphilis with different methods in which penicillin was employed are summarized as follows:

1. The outstanding result common to most of the patients in this series following the use of penicillin was a return of the cell count, protein and gold curve to within normal limits in the studies of the cerebrospinal fluid with reduction of the strength of the complement fixation and titer reactions of the blood.
2. The outstanding clinical effects as noted among patients who had objective and subjective signs of neurosyphilis were a gain of weight and a reduction of severity and frequency of the pains in the legs. The early symptoms of dementia paralytica were not influenced.
3. The patients who had meningeal neurosyphilis were most responsive both clinically and serologically, while patients who had the parenchymatous forms of the disease were helped only slightly if at all.
4. The outstanding serologic results noted were among the patients who had asymptomatic neurosyphilis and who received penicillin intravenously in doses approximating 1,200,000 units in a week, in association with either three spinal drainages or intraspinal treatments (Swift-Ellis type).
5. Penicillin given in combination with fever therapy, either malarial or by means of the fever machine, did not improve the clinical results noted from fever treatment alone.
6. The administration of penicillin by the intravenous, intramuscular or intraspinal route, alone or in combination with fever therapy, both malarial and by machine, leads us to believe that penicillin alone is not capable of controlling the parenchymatous forms of neurosyphilis. However, in cases of the meningeal forms of the disease and in those in which there was a high degree of pleocytosis in association with asymptomatic neurosyphilis, the results thus far are encouraging.
7. In occasional cases of neurosyphilis penicillin therapy produces clinical and serologic results that are outstanding. However, these favorable results are noted in only a few cases and often appear when least expected. It is not possible at this time to account for such great therapeutic discrepancies.

Physician's Obligation to Overweight Patients.—The patient who comes to the physician for reduction of weight must be *convinced* that (*a*) his obesity is due to eating more food than he requires, and (*b*) the only way *that* he can return to normal is by the slow, steady, difficult road of a proper diet. The patient should understand the danger of drugs for this condition and the futility of other methods of treatment. He should be told of the hazards of obesity, and *perhaps an appeal* may be made to his vanity or to his pride of his stamina and ability to manifest self control. It must be explained that the results will be achieved slowly and *will not* be spectacular. A diet list should be prepared which is as varied and enjoyable as possible, which furnishes bulk and ample vitamin requirements, and which has a caloric value of approximately 1,000 to 1,200 calories *daily*.—Smillie, Wilson G.: Preventive Medicine and Public Health, New York, Macmillan Company, *1946*.

THROMBOCYTOPENIC PURPURA IN PREGNANCY AND IN THE NEWBORN

WILLIAM B. PATTERSON, M.D.
Puunene, Maui, Hawaii

According to Polowe,[1] who reviewed the literature in 1944, 62 cases of pregnancy complicated by thrombocytopenic purpura have been reported. Most of the patients had no evidence of purpura before pregnancy, but at varying times during pregnancy acute hemorrhagic purpura developed with bleeding from all the mucous membranes and into the skin. The mortality was about 55 per cent for the mothers and was slightly higher for the infants. The maternal mortality was usually due to uterine bleeding following delivery, which was often premature. Some of the infants are reported to have died of hemorrhage and part of these were known to have had thrombocytopenia. That congenital thrombocytopenic purpura[2] may occur is suggested by the numerous cases reported in which both the mother and the infant have been affected. However, not all of the infants have been affected, and it may be that the tendency for thrombocytopenia is inherited. The patient who is the subject of this report is known to have had chronic purpura and thrombocytopenia since the age of 4. She became pregnant against medical advice but went through pregnancy normally except for postpartum hemorrhage, which was not too difficult to control. She had a healthy baby except that it has thrombocytopenia. Because of the danger of this complication of pregnancy, it was thought that this case should be recorded in detail so that thrombocytopenia might be suspected in patients who bleed after delivery from unknown cause.

REPORT OF CASE

History.—Mrs. C. M., aged 22, primigravida, referred to me in her fifth month of pregnancy by Dr. S. R. Wallis of Lihue, Kauai, T. H., is of Irish-German descent. Her maternal great-grandmother and grandmother were "bleeders." Her own mother, who bruises easily, had a severe postpartum hemorrhage requiring transfusion following her birth. A platelet count taken on Sept. 10, 1945 on her mother was 160,000 and the bleeding time was 3½ minutes. The patient has no sisters but has one brother who has shown no tendency to bleed.

At the age of 4 the patient fell and bruised her hip, and a large hematoma formed. Investigation revealed that she had a prolonged bleeding time and thrombocytopenia. Since that time she has always had purpuric spots on her body, which have usually formed where she bumps herself but sometimes they have formed without trauma. Her bleeding time has usually been much prolonged. During her childhood she had frequent nosebleeds, which occasionally required packing to control. She has had spontaneous bleeding from her gums at times, and tooth sockets have had to be packed after extractions. She first menstruated at 13 years of age and thereafter her menses came every twenty-eight days and lasted from seven to nine days. The flow was profuse for the first six days and was enough to saturate nine vulvar pads in twenty-four hours. At 19 years of age her menses were excessive and she became very anemic. At that time she consulted Dr. Ernestine Hamre, hematologist of Honolulu, T. H., who reported that the hemoglobin was 6 Gm., the blood platelets numbered 62,000 and the clot retraction was very poor in twenty-four hours. The hemoglobin returned to normal rapidly on treatment with ferrous sulfate.

Acc-Mo. 59

The first day of her last menstrual period was Sept. 11, 1944 and the expected day of delivery was June 18, 1945. She reported to me on Feb. 16, 1945. Physical examination was negative except for bruised spots on her legs and arms and showed a normal pregnancy of five months duration. The spleen was not palpable. The clotting time was 4½ minutes and the bleeding time was 8½ minutes. Her blood was type A and was Rh positive. The blood pressure and urine were normal and the blood Wassermann reaction was negative. She was given 3 grains (0.2 Gm.) of ferrous sulfate at mealtimes, 1 mg. of vitamin K daily and one polyvitamin capsule daily. She was put on a balanced diet including milk and iodized salt. The bleeding time was checked after one week and had dropped to 4 minutes, and after two weeks it had dropped to 2 minutes. Arrangements were made with two type A blood donors to give blood for transfusion in case of an emergency. The patient was warned to report any abnormal signs or symptoms immediately. She progressed normally except for a nosebleed lasting three minutes on April 14. She continued to get new purpuric spots wherever she bruised herself.

Normal labor began on June 12, which was six days before the expected date of delivery. After ten hours of labor, when the fetal head was fully engaged and the cervix was almost fully dilated, the patient was given 4½ grains (0.3 Gm.) of seconal and 90 cc. of rectal ether in oil. Thirty minutes after receiving this medication she was totally amnesic and quiet and did not require any further anesthesia. After twelve hours of normal labor the baby was delivered by low forceps, no episiotomy being necessary. A smooth solid blade obstetric forceps was used. The placenta complete with the membranes delivered spontaneously by the Duncan mechanism three minutes after the baby was born, and about 300 cc. of blood was lost at the time. After delivery of the placenta inspection revealed no tears of the cervix, vaginal walls, labia or perineum. There was no bleeding from the uterine cavity, and the vaginal mucosa appeared normal. Ergonovine maleate 1/320 grain (0.2 mg.) was given intramuscularly immediately after delivery of the placenta.

Fifteen minutes following delivery of the placenta a very slight amount of vaginal bleeding was noted, though the uterine fundus was very firm. Another dose of ergonovine maleate was given and the patient was put to bed. For the next hour the vaginal bleeding continued, though there was never more than a very slight flow of blood. Three vulvar pads became almost saturated in one hour. At this time the pulse rate was 120 per minute and the patient had become pale. The systolic blood pressure was 110 mm. of mercury. She was taken back to the delivery room, and the blood donors were called. The vagina was found to be filled with a large, firm blood clot which was attached to the vaginal walls. In removing the clot it was seen to extend through a ragged opening in the left vaginal wall and to be continuous with a clot in the tissue. The opening in the vaginal wall was at the exact location at which the left blade of the obstetric forceps had come in contact with the tissue, and it extended to the labia minora. It was not present at the time of inspection immediately following delivery of the placenta. There was very slight bleeding from the uterine cavity, but a steady stream of blood came from the rent in the vaginal wall. The tear in the vaginal wall was repaired with three sutures. The uterine cavity and the vagina were packed with 4 yards of heavy 3 inch gauze and the patient was given 1/6 grain (0.01 Gm.) of morphine sulfate. An intravenous infusion of 1,000 cc. of 5 per cent glucose in isotonic solution of sodium chloride was started and was followed by 500 cc. of citrated blood. When this treatment was completed after four hours the pulse had slowed down to 100 and was of good quality. The patient was awake and reacted normally for a patient who had had rectal ether eight hours previously.

The vaginal and uterine packs were left in for thirty-six hours, during which time there was slight bleeding through the packs. When the packs were removed there was still some bleeding, so the vagina was repacked. A blood count taken at this time showed 56 per cent hemoglobin with 2.5 million red blood cells. Another 500 cc. of citrated blood was given. The second vaginal pack was removed twenty-four hours after insertion, and thereafter there was only a normal amount of lochia. A blood platelet count made five days after delivery was 60,000, and a specimen of blood taken at this time showed no clot retraction in twenty-four hours. Ten days after delivery the platelet count was 34,640, the hemoglobin was 82 per cent, the red blood cell count was 4.3 million and the bleeding time was ½ minute.

During the puerperium the patient received 1/320 grain of ergonovine maleate every eight hours for three days and 3 mg. of vitamin K daily for eighteen days. She was able to nurse the baby normally. Her temperature did not go higher than 100 F. Vaginal examination on the eleventh postpartum day when the patient was discharged revealed that the involution of the pelvic organs was progressing normally. The tear in the vaginal wall had healed. Eighteen days after delivery the bleeding time was 6 minutes, and twenty-five days after delivery it was 3½ minutes. Thirty-seven days after delivery the bleeding time was 2 minutes, and the platelet count was *36,300.* Seventy-five days post partum the bleeding time was ¼ minute, and the platelet count was 90,000. The patient had vaginal discharge similar to menstrual flow from the twenty-eighth day after delivery until the forty-second day and from the seventy-seventh day until the eighty-third day.

Description of the Infant.—The baby was a normal boy and weighed 7 pounds 14½ ounces (3,586 Gm.) at birth. His spleen was not palpable. There was a faint mark on the right cheek where the forceps blade had pressed. He was offered his mother's breast and 2 ounces of sterile water every four hours. Sixty hours after birth it was noted that the forceps mark which had almost disappeared had suddenly become dark blue. Also there was one purpuric spot on his right forearm. The tourniquet test for petechiae was negative and there was no blood in the stool. He was given 2 mg. of vitamin K intramuscularly. Seventy-two hours after birth there were both streaks of blood and liquid blood mixed with the normal stool. A blood count revealed 118 per cent hemoglobin, 6.2 million red blood cells and 18,570 blood platelets. The coagulation time was 5 minutes, the bleeding time was 4 minutes and the blood was type A. He was given 50 cc. of pooled human plasma intravenously immediately and 30 cc. after twelve hours. Each succeeding stool contained less blood, so that there was none after thirty-six hours and the purpuric lesions gradually faded. On the tenth day after birth the platelet count was 28,800 and the bleeding time was ½ minute. He gained rapidly on breast milk and weighed 8 pounds (3,630 Gm.) on the eleventh day of life when he was discharged with his mother. On the thirty-seventh day of life the bleeding time was 1 minute and the platelet count was 20,820. On the seventy-fifth day of life the bleeding time was only ½ minute and the platelet count had risen to 175,000. He had had no purpuric spots since leaving the hospital and was developing normally.

COMMENT

To recognize and to diagnose thrombocytopenic purpura in pregnancy before an acute attack and before delivery, it is necessary to keep this complication in mind and to suspect it in all patients who have shown any abnormal bleeding tendency either before or during pregnancy. Patients who have had frequent nosebleeds or who bruise easily may have thrombocytopenia. Patients who have close relatives that are "bleeders" should be suspected. Patients who have had postpartum hemorrhage at a previous delivery should be suspected. Although in thrombocytopenic purpura the bleeding time and the platelet count may at times be normal, the bleeding time is usually prolonged and the platelet count is usually subnormal. The clotting time is normal, but clot retraction is very poor or absent in twenty-four hours. In the acute stage the tourniquet test is positive for petechiae.

The treatment of choice in acute hemorrhagic purpura is multiple small transfusions, preferably direct. Transfusions of about 200 cc. of blood should be given as often as is necessary, though at times larger transfusions [illegible] have to be given as a life saving procedure.

Library
G. M. S. Medical College
5

Some patients will continue to bleed after repeated transfusions, and in these splenectomy will usually be followed by an abrupt cessation of bleeding. However, splenectomy should be resorted to only as a life saving procedure and after conservative treatment has failed. Although there is usually an immediate improvement after splenectomy, time has demonstrated that this may be only temporary and that the patient may again develop acute hemorrhagic purpura. Splenectomy seems to be of most benefit for patients who have splenomegaly.

The development of late toxemia in a patient with thrombocytopenic purpura is a more serious complication than it is in a patient who is otherwise normal. The placentas of patients with late toxemia usually contain many infarcts, and these are often associated with a small amount of bleeding at the time of formation. It seems only logical to suppose that if the toxemic patient also has thrombocytopenia the bleeding that occurs at the time of placental infarction may continue and may lead to placental separation and to massive intrauterine hemorrhage.

Every pregnant patient who either has purpura or has a tendency to bleed should be hospitalized at the onset of labor. In the past almost all deaths of such patients have been caused by bleeding following delivery. Few of these patients bleed profusely at the time of delivery, but practically all of them bleed slowly and continuously for several hours or days following delivery. Owing to the abnormal clot formation the uterine sinuses continue to bleed although the uterine muscle is firmly contracted. The trauma produced by the fetus passing through the vagina is enough to cause bleeding beneath the vaginal mucosa of patients with thrombocytopenia. Enough bleeding may occur to produce a hematoma, which may rupture into the vagina and continue to bleed.

Patients who are known to have thrombocytopenia should have the uterine cavity and the vagina packed firmly with gauze immediately after delivery of the placenta. The pack should be left in for twenty-four to thirty-six hours. If vaginal bleeding recurs, the vagina should be inspected to see if the blood is coming from the uterus or from the vaginal walls. Then the uterus or the vagina or both should be repacked, depending on where the blood is coming from. Episiotomy is to be avoided on patients with thrombocytopenia unless absolutely necessary. To do an episiotomy on such a patient is to open another avenue of bleeding which may be very difficult to control.

All infants born alive to mothers with thrombocytopenia should be blood typed immediately, and the bleeding time and a blood platelet count should be made. The treatment of hemorrhagic purpura in newborn infants is the same as in any one else, namely, repeated small transfusions. The purpura and the bloody stools were observed in the infant of this report before there was any appreciable loss of blood, so pooled human plasma was given instead of blood. Although the infant in this case lost only 6 per cent of his body weight by the time the mother's milk was plentiful, he developed purpuric lesions and bloody stools after three days of starvation. He had the forceps bruise on his face from birth, but it did not become purpuric until the third day. As soon as he received an adequate amount of breast milk the bleeding stopped and has not recurred. It is very probable that the milk helped as much as the plasma.

After studying the subject of thrombocytopenia and pregnancy, one is forced to the conclusion that pregnancy is far too dangerous an undertaking for a woman who has chronic thrombocytopenic purpura. If a patient has an attack of acute thrombocytopenic purpura and recovers completely, as shown by a normal platelet count, normal bleeding time and normal clot retraction, pregnancy would not seem to be too great a risk. If pregnancy in a heretofore normal person is complicated by an acute attack of thrombocytopenic purpura, there seems to be little to gain by terminating pregnancy.

Clinical Notes, Suggestions and New Instruments

PRIVINE DEPENDENCE OF TWO YEARS' DURATION

LAWRENCE E. PUTNAM, M.D.
and
ROBERT P. HERWICK, Ph.D., M.D.
Washington, D. C.

Privine hydrochloride, a brand of naphazoline, was first described by Hild[1] in April 1941 as a preparation to reduce swelling of the nasal mucosa. Hild stated that "one important advantage of privine, compared with epinephrine, lies in the fact that it causes no reactive hyperemia and that it has only a relatively slight toxicity, if any." The drug appeared on the American market in October 1942. According to Fabricant and Van Alyea[2] "the 0.1 per cent solution of privine hydrochloride is a nontoxic nasal vasoconstrictor which has given satisfactory use in rhinologic practice." In August 1944 Gollom[3] reported persistent nasal congestion in more than 30 cases following the use of privine. Feinberg and Friedlaender[4] later reported over 75 cases in which symptoms of nasal congestion were aggravated or prolonged by the continued use of privine. The following case may be of the longest duration which has yet been noted:

Mrs. B. E., aged 35, a housewife, was seen on Oct. 31, 1945 complaining of nasal obstruction of two years' duration. In 1934 and 1937 she had had some treatment for sinus trouble. In December 1943 she noticed nasal congestion and tried several home remedies which did not seem to work very well. She then saw a nose and throat specialist, who recommended privine. This seemed to give her remarkable relief, but this lasted only about three to four hours each time and she continued to use the product every three to four hours for a total of 1 ounce weekly. A short time later the patient saw another physician, who recommended the use of different nose drops, but these gave poor relief so she reverted to the use of privine. In July 1945, after seven months of continuous use of this preparation, she returned to a city on the West Coast, where she saw her family doctor. He irrigated her sinuses with mild protein silver and prescribed thyroid without relief of the nasal congestion. In September 1945 she saw a nose and throat specialist, who said there was no sign of infection in her sinuses at that time, merely swelling of the mucous membranes.

She continued to use privine until she was seen in October 1945. Physical examination was essentially negative except for some tenderness of both frontal sinuses and both antrums. The mucous membranes of the nose were somewhat pale, but there was no congestion (the patient had had her usual dose of privine about two hours previously).

From the Food and Drug [illegible] Federal Security Agency.

[2] Fabricant, N. D., and Van Alyea, O. E.: A Note on the Evaluation of Privine HCl as a Nasal Vasoconstrictor, Am. J. M. Sc. 205: 122-125 (Jan.) 1943.

[3] Gollom, J: The Problem of Nasal Medication, with Particular Reference to Privine Hydrochloride 0.1 Per Cent, Canad. M. A. J. 51: 123-126 (Aug.) 1944.

[4] Feinberg, S. M., and Friedlaender, Sidney: Nasal Congestion from Frequent Use of Privine Hydrochloride, J. A. M. A. 128: 1695 [illegible] (Aug. 11) 1945.

Since it was felt that the original cause of the patient's nasal congestion had long since disappeared and that the present difficulty was due to the compensatory reaction following nasal decongestion, it was recommended that she discontinue privine completely To prevent any possible headache or other symptoms due to withdrawal of the drug, she was given a supply of ephedrine capsules, 3/8 grain (0 024 Gm) each, for use during the day and ephedrine with a barbiturate for use in the evening or at night The patient was quite apprehensive about discontinuing the privine, since she had depended on it so completely for the past twenty three months However, she agreed to stop it and to use acetylsalicylic acid liberally if any headache developed On arising the following morning her nose was somewhat blocked and she took one capsule of ephedrine That night she took one of the ephedrine-barbiturate capsules because of some nasal congestion and a fear that she would not be able to sleep The following day, after she had entered a smoky room, her nose became congested again and she took a second ephedrine capsule without any noticeable benefit She obtained relief by leaving the room For the next four nights she took one of the ephedrine-barbiturate capsules before going to bed She then discontinued all medication and until the present (three months later) has had to use none at all The nasal mucous membrane at this time appears essentially normal

SUMMARY

1 A case of privine dependence of twenty three months' duration was observed

2 Privine and other potent nasal decongestants are valuable when used properly

3 To avoid dependence on these drugs they should be discontinued as soon as the immediate need for them disappears

TREATMENT OF UREMIA AFTER ACUTE RENAL FAILURE BY PERITONEAL IRRIGATION

HOWARD A FRANK, M D, ARNOLD M SELIGMAN, M D
and
JACOB FINE, M D
Boston

Uremia resulting from acute renal damage is frequently fatal, because the renal lesion requires more time for healing than the lethal effects of the uremia will permit Such potentially reversible renal lesions include those resulting from incompatible transfusions, sulfonamide toxicity massive trauma, suppression of kidney function following surgical trauma to the urinary tract, toxemia of pregnancy mercury poisoning and certain forms of acute glomerulonephritis

Available methods do not provide for sufficient excretion of retained substances by extrarenal pathways Clearance of the circulating blood through an artificial dialyzing membrane is one of the recent methods advocated[1] But the technical difficulties involved, the need of adequate heparinization and the additional vascular load such a method imposes are serious handicaps to the acceptance of this method

The use of the peritoneum as a dialyzing membrane for extrarenal excretion is not new Efforts to utilize this structure to treat uremia have been made in animals and in a few instances in man but without success

In a preliminary study[3] we observed that a properly performed peritoneal irrigation can remove crystalloids from the blood with an efficiency adequate to substitute for renal function and to sustain life for many days The fluid for irrigation is designed to avoid depleting the plasma of its electrolytes and glucose and to combat acidosis[4] It is mammalian Tyrode's solution to which is added penicillin for bacteriostasis of susceptible organisms, heparin to inhibit fibrin deposition in the peritoneal cavity and additional glucose The technic developed and the experimental findings are described in detail elsewhere[3] Briefly, it consists in the introduction of an inlet and outlet tube into the peritoneal cavity through incisions under local anesthesia The sterile solution, prepared in large volume (20 to 35 liters per day), is run in by gravity at a controlled rate for maximum urea clearance of the blood and drained from the peritoneal cavity as fast as it enters the outlet tube The outlet tube is a stainless steel sump drain[5] attached to a continuous suction system to draw out fluid as rapidly as it collects

We report herewith a successful application of peritoneal irrigation to a patient who was expected to succumb to uremia following parenchymatous injury to the kidneys from sulfathiazole administration

REPORT OF CASE[6]

H Y, a man aged 51, entered the hospital complaining of headache, nausea, vomiting, diarrhea, a skin rash and oliguria of five days' duration Following a transurethral prostatectomy and resection of a bladder diverticulum one year earlier he had contracted asymptomatic pyuria, which persisted intermittently thereafter Sulfadiazine therapy had been given postoperatively but not thereafter Three weeks before the present admission he developed a painful tender swelling in the right groin, diagnosed as an inflammation of the vas deferens, for which 4 Gm of sulfathiazole daily was prescribed This dose was taken daily for fourteen days prior to hospital entry Five days before admission oliguria was first noted, and for three days before admission he was virtually anuric (30 cc output per day)

On admission the patient was semistuporous A maculopapular rash was present on the trunk and extremities The abdomen was distended with fluid The rectal temperature was 102 8 F, deep respirations were 25 to 30 per minute the pulse rate was 114 per minute, the blood pressure 136/86, the red blood cell count 4 6 million, hemoglobin 13 6 per hundred cubic centimeters, the white blood cell count 9,900 (70 per cent polymorphonuclear cells, 26 per cent lymphocytes) A chest film showed probable bronchopneumonia of the left lower lobe

Penicillin 25,000 units was given every three hours The temperature became normal by the third hospital day and remained so thereafter

During the first four hospital days the daily urine output was 30 cc, 200 cc, 0 cc and 0 cc respectively Oral fluid was supplemented with intravenous 5 per cent glucose in water until the daily intake ranged from 5 to 7 liters per day Increased ascites and generalized edema developed

On the third hospital day cystoscopy revealed edema and inflammation of the bladder mucosa Ureteral catheterization disclosed no obstruction of the ureters The renal pelves were empty and no crystals were found The urologist (Dr E G Crabtree) considered the situation due to parenchymatous injury from sulfathiazole and the outlook grave

On the fifth hospital day the patient's condition was critical He was delirious and stuporous, distended and acidotic and had generalized and pulmonary edema The blood nonprotein nitrogen was 185 mg per hundred cubic centimeters, the blood urea nitrogen 126 mg per hundred cubic centimeters and the plasma carbon dioxide combining capacity 23 volumes per cent The patient was referred to us for treatment

Peritoneal irrigation was instituted A mushroom catheter was inserted on one side, and a sump drain on the other side of the peritoneal cavity Considerable ascitic fluid with a urea content of 92 mg per hundred cubic centimeters was aspirated

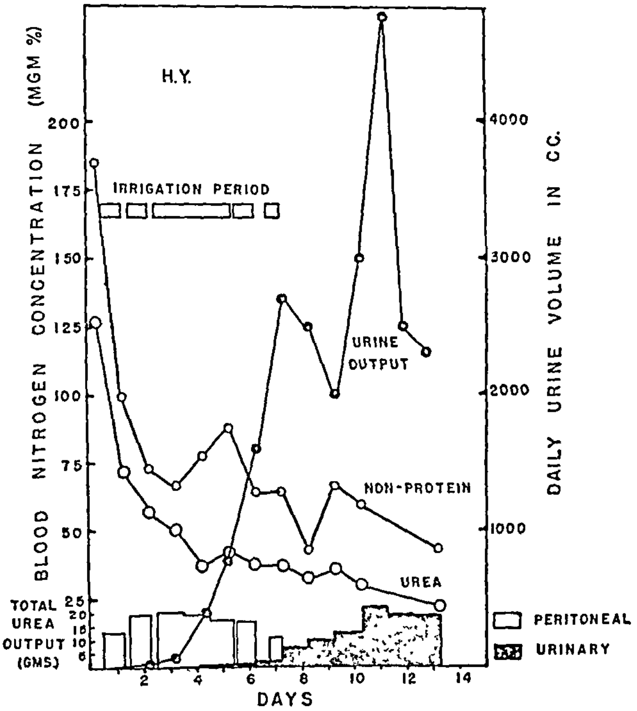
[6] *Dr Louis Kraner referred this patient to us for treatment*

The peritoneal irrigation was conducted without difficulty and produced no discomfort. All outflow fluid was collected.

The accompanying chart shows for each day the changes in blood level of nonprotein and urea nitrogen, the volume of urine excreted and the total amount of urea present in the peritoneal drainage fluid and in the urine. The table shows the concentrations of urea in urine and in peritoneal drainage fluid, together with the calculated urea clearances. Blood sodium chloride remained high (660 mg. per hundred cubic centimeters).



Changes observed each day.

On the fourth day of irrigation after fourteen days of oliguria or anuria the urine volume increased to 400 cc. Thereafter the volume excreted increased steadily. The specific gravity of the urine remained low (1.005 to 1.010) throughout the period of observation, but the urea concentration in the urine, which at first was no higher than that of the plasma, steadily rose until it reached 400 mg. per hundred cubic centimeters on the day of discharge from the hospital. Urinary urea clearance values improved steadily but remained well below normal values up to the time of discharge.

On admission the small amounts of urine excreted were alkaline in spite of the patient's acidosis. When diuresis started, the urine became acid. The urine on admission showed the Friedlaender bacillus and many white cells. Throughout the period of observation the urine contained small to moderate amounts of albumin and white cells but no red cells, casts or crystals.

Clinical improvement, except for the aggravation of symptoms of ileus on the third day, paralleled that of the clinical chemistry. Acidosis persisted, probably on a starvation basis. Therefore 400 Gm. of glucose was added to the irrigation fluid on the fourth day of irrigation, and by the fifth day the carbon dioxide combining capacity had risen to 40 volumes per cent.

Since the patient had received large volumes of fluid before irrigation was started and was edematous as a result, intravenous fluid therapy during the first two days of irrigation was cut to 2,000 to 3,000 cc. of 10 per cent glucose in water daily, to provide additional carbohydrate. It was felt that the patient could dispose of the excess interstitial fluid and the intravenous fluid through the peritoneal pathway. But when the slight degree of pulmonary edema previously present increased on the third day of irrigation, all intravenous therapy was stopped for the subsequent forty-eight hours. Thereafter, when the evidence of pulmonary edema had disappeared, glucose and amino acids were supplied intravenously as required.

At about the same time (the third day of irrigation) polymorphonuclear cells and colon and paracolon bacilli appeared in the peritoneal drainage fluid. This plus the increase in the signs and symptoms of ileus suggested the onset of peritonitis. Miller-Abbott tube therapy was started. After drainage through the Miller-Abbott tube of some 3,000 cc. of fluid daily for two days, edema decreased. Penicillin administration and peritoneal irrigation were continued. The patient showed mental depression but no clinical evidence of sepsis; he remained afebrile with a normal pulse and a normal total and differential white blood cell count. Edema disappeared by the fifth day of irrigation, and the patient was much improved except for mental depression, recurring intestinal distention and intolerance to food by mouth. As the volume and quality of urine improved, the irrigation was performed intermittently and was discontinued entirely seven days after it was started. The following morning the nonprotein nitrogen was 43 mg. per hundred cubic centimeters and the blood urea nitrogen 33 mg. per hundred cubic centimeters. The irrigation tubes were removed without discomfort. Mild wound sepsis was present, but the wounds healed rapidly.

Because the organisms growing in the peritoneal fluid were not susceptible to penicillin, streptomycin[7] (which was found to be effective in vitro in a concentration of 500 units per cubic centimeter against the organisms involved[8]) was injected into the peritoneal cavity (1 million units in 1 liter of saline solution) the day after termination of the irrigation and again on the subsequent day. There was no unfavorable reaction to this procedure.

It is not possible to evaluate the effect of streptomycin because there was no evidence of peritonitis aside from the presence of leukocytes and bacteria in the drainage fluid, and ileus. However, the patient's mental depression and ileus cleared considerably thereafter. General improvement continued, the Miller-Abbott tube was removed and the patient was able to take a full diet and 3,000 to 5,000 cc. of fluid orally per day. The specific gravity of the urine remained low, 1.008 to 1.012. The patient was up and about, normal mentally and feeling well, although he showed a moderate anemia (red blood count 3.6 million, hemoglobin 70 per cent). He was discharged from the hospital a week after peritoneal irrigation was stopped.

At the time of discharge renal function, in terms of urea clearance, was about one third of normal and was improving

† Clearance (C) calculated from equation (Moller, McIntosh and Van Slyke: J. Clin. Investigation 6:427, 1928) $C = \frac{UV}{B}$, where V equals the rate of flow (cc. per min.) of peritoneal fluid or urine, U equals the urea nitrogen concentration (mg. per hundred cubic centimeters) of peritoneal fluid or urine, and B equals the urea nitrogen concentration (mg. per hundred cubic centimeters) of blood. The value of B at the end of each collection period of urine or peritoneal fluid was used in the calculation.

[7] Dr. D. F. Robertson of Merck & Co. supplied the streptomycin.

[8] Dr. Fritz Schweinburg performed this test.

daily. It was adequate to maintain normal blood levels of nitrogenous substances and to prevent acidosis. The phenolsulfonphthalein excretion test showed 20 per cent excretion in one and three-fourths hours, i. e. about one third of the normal value. Four weeks later the renal urea clearance was greater than half of normal and the phenolsulfonphthalein excretion was normal.

COMMENT

Peritoneal irrigation in this patient corrected uremia and provided an adequate substitute for renal function until recovery of renal function occurred. Clinical improvement followed closely the progressive improvement in blood chemistry. We cannot state with finality that the patient would have died without peritoneal irrigation. In any case the incidence of recovery from acute renal failure will doubtless be increased by any method that eliminates the uremic state and its serious complications early.

The chart and table demonstrate the progressive recovery of renal function which began fourteen days after kidney shutdown and the fourth day after peritoneal irrigation was started. The volume output became normal shortly after diuresis began, but the recovery of concentrating function was slower. At the time the patient was discharged, urea clearance and phenolsulfonphthalein excretion were only some 30 per cent of normal. This, however, was adequate to keep the blood urea and nonprotein nitrogen levels within normal limits. Further improvement in renal function occurred in the following four weeks. Sufficient time has not elapsed to determine the full extent of return of renal function.

The speed with which peritoneal irrigation lowers the blood level of retained excretory products depends on the amount stored in extravascular compartments and will vary with the body weight and degree of edema. It also depends on the rate of flow of the irrigating fluid. Data obtained from other patients [9] show that the flow rate is optimal between 40 and 60 cc. per minute. At this rate 15 to 20 Gm. of urea can be removed in twenty-four hours, which is equivalent to the average rate of urea production on a normal diet and considerably exceeds that on a low protein diet. The efficiency of peritoneal irrigation does not diminish with time.

In the treatment of this patient the peritoneal drainage flow rate averaged 25 cc. per minute and the daily urea output varied from 12 to 20 Gm. per day. The blood urea clearance by peritoneal irrigation averaged 14.8 cc. of blood per minute and was as high as 21 cc. per minute. This was sufficient to correct the uremic state. An average peritoneal irrigation urea clearance value of 15 cc. per minute ordinarily should be an adequate renal substitute, because not more than 10 per cent of the average normal "maximum" renal urea clearance value (75 cc. per minute) is necessary to prevent the accumulation of excretory products.[10] Hence peritoneal irrigation may be discontinued when a patient of average size, on a normal or less than normal protein intake, is free of uremia and the recovery of renal urea clearance of the blood equals or exceeds 7.5 cc. per minute.

The primary hazard in and the only important limitation to the use of peritoneal irrigation is the danger of peritonitis. Peritonitis probably did develop in the case reported, for gram-negative organisms and leukocytes were found in the peritoneal drainage fluid, and the ileus already present seemed to grow worse. However, no other evidence of peritonitis was present.

The possible sources of peritoneal contamination by organisms are several: (1) errors in preparation of sterile fluid and apparatus, (2) contamination while shifting attachments to refilled carboys and (3) possible entry of organisms from the skin along the tube tracts or from room air through the sump drain. The first two errors can be largely counteracted by the use of bacterial filters in the delivery circuit. A thick gauze dressing is used as an air filter over the sump. As a further precaution antibacterial chemotherapy is used by giving penicillin intramuscularly as well as in the irrigating fluids for gram-positive organisms and streptomycin for gram-negative organisms. Improperly prepared solutions may be irritating to the intestinal serosa and thereby might facilitate the migration of bacteria from the intestine into the peritoneal cavity; properly prepared solutions seem not to impair the integrity of the peritoneum. Considering the gravity of the problem faced in uremia, the hazard of peritonitis should not discourage the use of the method if all precautions are taken.

The implantation of the tubes constitutes a minimal surgical trauma, which can be performed with virtually no risk in any phase of the patient's illness. Patients in uremia commonly have ileus or other gastrointestinal disturbances. Whether the irrigation process adds to these symptoms is not certain, but the symptoms are manageable by the usually available technics.

The free exchange of water and electrolytes between the plasma and the peritoneal fluid largely eliminates the need of routine intravenous fluid therapy. It is unlikely that unrestricted water administration speeds the recovery of kidney function. If caution is not exercised in the parenteral administration of fluids during the oliguric phase, especially if acidosis is present, lethal pulmonary edema may be produced. Unless the patient can take food orally, however, supplementary glucose, amino acids and vitamins should be given parenterally.

CONCLUSION

Peritoneal irrigation, by the technic herein described, eliminated uremia following acute renal failure from parenchymatous injury caused by sulfathiazole. Recovery of sufficient renal function to prevent the recurrence of uremia took place.

SUDDEN DEATH IN STATUS LYMPHATICUS

The British investigators Greenwood and Woods[1] characterize status lymphaticus as "this heap of rubbish," stating furthermore that "the present use in certification and in evidence in coroners' courts of the phrase Status Lymphaticus and Status Thymic Lymphaticus is . . . a good example of the growth of medical mythology. A nucleus of truth is buried beneath a pile of intellectual rubbish, conjecture, bad observations, rash generalization." The British commission headed by Young and Turnbull[2] was unable to locate in status lymphaticus even a "nucleus of truth" and concluded that no such condition exists. Elsewhere status lymphaticus is regarded as a clinically recognizable entity consisting of "a combination of hereditary constitutional anomalies, entering into which are certain peculiarities of configuration, with preservation or even hyperplasia of the thymus at an age when involution is to be expected, hyperplasia of the lymphoid cells in the spleen, intestine and elsewhere, changes in the distribution of hair, hypoplasia of the vascular system, developmental deficiencies in the genitalia and, incidentally, visceral defects of uncertain occurrence and irregular distribution."[3]

In children suddenly dead with the physical attributes of status lymphaticus the lymphoid tissues in various parts of the body show myriads of necroses in the cells of the germinal follicles. These changes are believed to result in the release of sensitizing nucleoproteins. After the expiration of the anaphylactic incubation period the lymph nodes, according to this theory, are again subjected to the action of destructive substances which now serve to bring about further disintegration of nuclei, thus providing the requisite quantity of specific proteins to complete the anaphylactic cycle and to bring about sudden death.[3] Another theory of sudden death in subjects of status lymphaticus involves pressure effects. At Bellevue Hospital, where for a good many years status lymphaticus has been a subject of systematic study not only by the hospital pathologists but by medical examiners engaged in the investigation of sudden death, the anatomic signs of tracheal compression and of death from suffocation, although sought, have never been found. In the Bellevue necropsy experience the heaviest thymus encountered in status lymphaticus weighed 115 Gm., whereas the weight necessary for compressing the trachea, as shown by the experiments of Tamassia, is at least 180 Gm.

Carr[4] of the San Francisco Coroner's Office has described a series of 7 cases of status lymphaticus in which he believes that death was due to asphyxia following tracheal obstruction and displacement of the heart and lungs by the enlarged thymus gland. Perhaps the mere existence of the anatomic composite of status lymphaticus does not always satisfactorily explain the cause of sudden death.

If, as suggested by the British commission, status lymphaticus should be withdrawn from further consideration, it would exclude an apparently important antecedent of sudden death and, to this extent, progress would cease.

THERAPY OF FILARIASIS BANCROFTI

In a report on the medicinal treatment of filariasis bancrofti, Temkin[1] stresses the protean character of the earliest symptoms of filariasis and the difficulty of diagnosis, particularly in the differentiation from pseudofilariasis. Attacks of lymphedema, lymphadenitis and lymphangitis of one form or another constitute the early symptoms of filariasis in the Pacific. The recognition of the existence of "primary elephantiasis" suggests that the absence of early symptoms is no guaranty against a development of this complication. However, elephantiasis, even in native populations constantly exposed to infection, is relatively limited in incidence. Immunologic tests have not reached the stage where they could unequivocally decide the diagnosis of filiarasis. Therefore the efficacy of any drug must be judged by its effect on the disease as a whole. The bacterial theory of the disease, which denies the primary importance of filariasis, is not supported by experience from the application of sulfonamide drugs. Most authors do not regard either secondary infection or microfilariae as essential in the pathogenesis of the disease. Attention centers around the adult parasite and the body reaction to filarial infection itself. O'Connor believes that the acute inflammatory attacks represent an allergic or anaphylactic reaction, whereas elephantiasis is due to mechanical obstruction caused directly or indirectly by the worms or embryos. This theory presupposes the existence of hyperfilariation and the death and disintegration of large numbers of parasites at different times. O'Connor argues that antimony and arsenicals administered intravenously are ineffective because the parasites are not in the blood stream and, if degenerating, are largely cut off from circulation. The symptoms of early filariasis are partly allergic and partly due to inflammatory reactions caused by the adult worm. It is not possible to tell whether dead or living worms are preponderantly responsible for the pathologic changes.

[1] Temkin, Owsei: A Report on the Medicinal *Treatment of Filariasis* Bancrofti, National Research Council, Washington, D. C., September 1945.

Filariasis has a relatively good prognosis if reinfection is prevented and the patient is put under favorable clinical, physical and psychologic conditions. A majority of investigators aimed at the destruction of the living adult worms. The effectiveness of the drugs was tested on parasites in vitro, on related filarial infection in animals, on clinical symptoms and on microfilariae in the blood of man. Animal experiments were made on naturally occurring infections in dogs with Dirofilaria immitis and on Florida cotton rats infected with Litomosoides carinii. Culbertson and Rose obtained rather encouraging results with neostam and neostibosan in animal experiments. The adult worms appeared more susceptible to the action of these drugs than were the microfilariae. The latter disappeared gradually in the course of the treatment, but the adult worms were usually dead two weeks from the beginning of the treatment. In 1940 patients with filariae were given fuadin, anthiomaline, antimony, neoarsphenamine, acetylarsan, espundal, arsant, emetine, sulfanilamide, 4:4-diaminodiphenyl-sulphone, glucoside by Hawking. No filaricidal action could be demonstrated, judging by the persistence of microfilariae in the blood stream.

Hawking thought it possible that a drug might kill the adult worms without at the same time damaging the microfilariae. Culbertson and his associates administered neostibosan intravenously to 30 native Puerto Ricans infected with Wuchereria bancrofti With the exception of 1 patient suffering from periodic chyluria, all were rendered symptom free. The treatment lasted from thirty-three to forty-eight days. Of the 30 patients treated, 13 had lost all microfilariae twelve months after the end of the treatment, and 5 had lost between 87 and 99 per cent of the microfilariae. In the remaining 12 patients the microfilariae had declined from 4 to 74 per cent after nine months of observation. In a control group of 15 patients, 3 showed increases from 3 to 1,200 per cent during fourteen months of observation. When the actual course of treatment had ended, the microfilaria levels of the patient showed little or no change. The microfilaria levels were maintained or continued to decline for twelve months after the end of the treatment. The authors suggest that this slow action may be attributable to a direct action of neostibosan on the adult parasites rather than on the microfilariae.

The experience with various chemotherapeutic agents indicates that antimony compounds still hold the highest promise of all the drugs tried.

THE LIVER AND SHOCK

Shock may arise following a variety of clinical accidents. This divergence of initiating factors has given rise to a number of theories regarding the fundamental cause of shock. Some attribute the situation to toxic substances produced by tissues injured mechanically or through hypoxia; a good case can be made for a strictly neurogenic origin of the shock syndrome; drastic alteration in the usual pattern of hemodynamics is considered a reasonable basis for the development of shock. A more recent tendency, stimulated by studies in connection with the war, has been to link the causes of the recognized changes in intermediary metabolism in shock with the origin of this syndrome. In this connection the liver has been implicated in the cause of shock.

Shock produced in experimental animals is followed by a definite delay in regeneration of serum protein,[1] an observation which raises the question of the place of the liver in the development of the shock syndrome. In the shock produced by restriction of blood flow to an extremity, hepatic glycogen decreases considerably and its synthesis from administered glucose is greatly delayed.[2] Furthermore, the observation that increased levels of lactic and pyruvic acid can be demonstrated in the blood in hemorrhagic shock,[3] calls attention again to the liver in this abnormal state. Whereas the liver ordinarily has a large capacity for the metabolic transformation of amino acids, Engel and his co-workers [4] have shown that a well defined rise in the concentration of amino acids occurs in the blood of animals in shock as a result of hemorrhage and that the rate of urea formation from amino acids is also depressed. It has been suggested that the loss of potassium from body cells may be the "toxic factor" in shock.[5] Recently Darrow and Engel [6] have investigated the shifts of electrolytes and water between cells and extracellular fluids in the liver following hemorrhagic shock. It appears that an early result of the loss of blood is a shift of water from the hepatic cells to the extracellular spaces and a concomitant loss of potassium from the cells. During recovery there is a tendency to replace the lost potassium, but complete restoration of the composition of the liver is not observed.

[6] Darrow, D. C., and Engel, F. L.: Am. J. Physiol. **145**: 32, (Nov.) 1945.

The foregoing experimental evidence appears to implicate the liver in the development of shock. However, the Yale investigators [6] believe that this organ is readily influenced by hypoxia and that the improvement in circulation and the consequent restoration of the supply of oxygen will restore normal hepatic function. The liver is involved in so much of the metabolic picture of the body that it is not unexpected to find that these chemical transformations are changed in shock. Any claim that the liver bears a primary causative relation to this condition would seem to require further demonstration.

Current Comment

MILITARY DEATHS IN WORLD WAR II

The exact number of military deaths in World War II probably never will be known accurately. Indications are that they exceed those in World War I, which are estimated at about 8,000,000. According to a recent discussion of this subject,[1] the combat loss of belligerents in World War II was from 9,500,000 to 10,000,000. The losses of the Axis powers have been estimated at about 5,200,000, of which number Germany contributed 3,250,000, Japan 1,500,000 and Italy 150,000 to 200,000. The complete death losses of the United Nations are estimated in the neighborhood of 4,500,000, of which approximately 3,000,000 were Russian and about 400,000 British Empire deaths. Of the British Empire losses, about 250,000 were residents of the United Kingdom. The final total of United States losses on all fronts in World War II is not yet completed but is probably close to 325,000. Even though the compilations are incomplete and inaccurate, World War II was by far the most destructive in human history in terms of loss of life as well as in many other respects.

INSECT CONTROL

The Coordination Center of the Insect Control Committee, National Research Council, has prepared an Abstract Bulletin to provide abstracts of "open" reports on insect and rodent control. Several issues will be prepared. The reports were received from government agencies, the armed forces, universities and other sources. Inquiries may be addressed to the Coordination Center, National Research Council, Insect Control Committee, 2101 Constitution Avenue, Washington 25, D. C. The contents in the first issue are grouped under biology, chemistry, dispersal, entomology, rodent control and general. For security and other reasons little of this information was disseminated during the war. With the end of war, security restrictions have been removed but lack of journal space may delay publication of many of the more important articles. This bulletin provides a real service by making the information available as soon as possible.

HODGKIN'S DISEASE AND GIANT FOLLICULAR LYMPHADENOPATHY

A disease which simulates Hodgkin's granuloma and which, unlike it, is susceptible of cure is the comparatively newly discovered giant follicular lymphadenopathy, known also as giant follicle hyperplasia of lymph nodes and spleen and giant follicular lymphoma. This disease is characterized by enlargement of lymph nodes in various parts of the body, usually most noticeable in the superficial areas, and by splenomegaly, the enlargements in both places being due to dimensional and numerical hyperplasia of lymph follicles. Histologically, giant follicular lymphadenopathy is strikingly different from Hodgkin's disease; the microscopic distinction may be made at a glance. It differs also from Hodgkin's disease in that it is curable by mild x-ray therapy, whereas Hodgkin's disease is not amenable to any method of treatment at present known. At the moment it appears that giant follicular lymphadenopathy is well recognized by pathologists, but there are clinicians who seem never to have heard of it. Symmers [1] and Morehead and Woodruff [2] have recently shown that there is a lesion of the lymph follicles of the appendix in which the microscopic changes are identical with those of giant follicular lymphadenopathy or of giant follicular lymphadenopathy with rupture and transformation of the hyperplastic follicles into so-called polymorphous cell sarcoma, giving rise in either event to the symptoms of appendicitis.

ADRENAL HYPERTENSION

The possibility that adrenal ischemia may cause arterial hypertension was tested recently by Victor[1] and his associates of the Goldwater Memorial Hospital, Columbia University. The left adrenal glands of 6 dogs were exposed, and many of the arterioles entering the gland from the pericapsular fat and connective tissue were ligated. One ligature was placed about the vascular fat and connective tissue containing the hilar artery and vein, and a second ligature about the grossly visible arteries and veins entering either the superior or the inferior pole. Systolic and diastolic blood pressures were recorded daily before and after the operation. Before the operation the average systolic pressure was in the neighborhood of 125 mm. of mercury for all dogs. Within two weeks after the operation the average was as high as 225. There was a slight subsequent rise in systolic pressure, the pressure going as high as 280 in 1 dog. In all dogs the elevated blood pressure has persisted till the present time (seven months after the first operation). Chemical and microscopic studies are not yet completed. Evidently, however, in dogs unilateral suprarenal ischemia due to subtotal ligation of periadrenal blood vessels causes a prompt and sustained hypertension, comparable with the hypertension produced by experimental renal ischemia (Goldblatt clamps).

NATIONAL HEALTH PROGRAM OF THE AMERICAN MEDICAL ASSOCIATION

Adopted by the Board of Trustees and the Council on Medical Service, Feb. 14, 1946

1. The American Medical Association urges a MINIMUM STANDARD OF NUTRITION, HOUSING, CLOTHING AND RECREATION as fundamental to good health and as an objective to be achieved in any suitable health program. The responsibility for attainment of this standard should be placed as far as possible on the individual, but the application of community effort, compatible with the maintenance of free enterprise, should be encouraged with governmental aid where needed.

2. The provision of PREVENTIVE MEDICAL SERVICES through professionally competent health departments with sufficient staff and equipment to meet community needs is recognized as essential in a health program. The principle of federal aid through provision of funds or personnel is recognized with the understanding that local areas shall control their own agencies as has been established in the field of education. Health departments should not assume the care of the sick as a function, since administration of medical care under such auspices tends to a deterioration in the quality of the service rendered. Medical care to those unable to provide for themselves is best administered by local and private agencies with the aid of public funds when needed. This program for national health should include the administration of MEDICAL CARE, INCLUDING HOSPITALIZATION TO ALL THOSE NEEDING IT BUT UNABLE TO PAY, such medical care to be provided preferably by a physician of the patient's choice with funds provided by local agencies with the assistance of federal funds when necessary.

3. The procedures established by modern medicine for advice to the prospective mother and for ADEQUATE CARE IN CHILDBIRTH should be made available to all at a price that they can afford to pay. When local funds are lacking for the care of those unable to pay, federal aid should be supplied with the funds administered through local or state agencies.

4. The child should have throughout infancy PROPER ATTENTION, INCLUDING SCIENTIFIC NUTRITION, IMMUNIZATION AGAINST PREVENTABLE DISEASE AND OTHER SERVICES INCLUDED IN INFANT WELFARE. Such services are best supplied by personal contact between the mother and the individual physician but may be provided through child care and infant welfare stations administered under local auspices with support by tax funds whenever the need can be shown.

5. The provision of HEALTH AND DIAGNOSTIC CENTERS AND HOSPITALS necessary to community needs is an essential of good medical care. Such facilities are preferably supplied by local agencies, including the community, church and trade agencies which have been responsible for the fine development of facilities for medical care in most American communities up to this time. Where such facilities are unavailable and cannot be supplied through local or state agencies, the federal government may aid, preferably under a plan which requires that the need be shown and that the community prove its ability to maintain such institutions once they are established (Hill-Burton bill).

6. A program for medical care within the American system of individual initiative and freedom of enterprise includes the establishment of VOLUNTARY NONPROFIT PREPAYMENT PLANS FOR THE COSTS OF HOSPITALIZATION (such as the Blue Cross plans) and VOLUNTARY NONPROFIT PREPAYMENT PLANS FOR MEDICAL CARE (such as those developed by many state and county medical societies). The principles of such insurance contracts should be acceptable to the Council on Medical Service of the American Medical Association and to the authoritative bodies of state medical associations. The evolution of voluntary prepayment insurance against the costs of sickness admits also the utilization of private sickness insurance plans which comply with state regulatory statutes and meet the standards of the Council on Medical Service of the American Medical Association.

7. A program for national health should include the administration of MEDICAL CARE, INCLUDING HOSPITALIZATION, TO ALL VETERANS, such medical care to be provided preferably by a physician of the veteran's choice, with payment by the Veterans Administration through a plan mutually agreed on between the state medical association and the Veterans Administration.

8. RESEARCH FOR THE ADVANCEMENT OF MEDICAL SCIENCE is fundamental in any national health program. The inclusion of medical research in a National Science Foundation, such as proposed in pending federal legislation, is endorsed.

9. The services rendered by VOLUNTEER PHILANTHROPIC HEALTH AGENCIES such as the American Cancer Society, the National Tuberculosis Association, the National Foundation for Infantile Paralysis, Inc., and by philanthropic agencies such as the Commonwealth Fund and the Rockefeller Foundation and similar bodies have been of vast benefit to the American people and are a natural outgrowth of the system of free enterprise and democracy that prevail in the United States. Their participation in a national health program should be encouraged, and the growth of such agencies when properly administered should be commended.

10. Fundamental to the promotion of the public health and alleviation of illness are WIDESPREAD EDUCATION IN THE FIELD OF HEALTH and the widest possible dissemination of information regarding the prevention of disease and its treatment by authoritative agencies. Health education should be considered a necessary function of all departments of public health, medical associations and school authorities.

MEDICINE AND THE WAR

VETERANS

VETERANS ADMINISTRATION RECRUITMENT OF PHYSICIANS

The enactment of Public 293, which created the new Department of Medicine and Surgery of the Veterans Administration, has proved most helpful in the procurement of physicians, dentists and nurses In the first six weeks of the operation of this law 797 new physicians have accepted appointment

Of the newly appointed physicians, 57 are specialists certified by one or another of the approved examining boards These include

American Board of Internal Medicine	17
Neuropsychiatry	16
Radiology	6
Otolaryngology	5
Surgery	4
Pathology	4
Ophthalmology	2
Urology	2
Gynecology and Obstetrics	1

It is most encouraging that the proportion of applications from certified specialists is constantly increasing The professional opportunities offered in the remodeled medical service of the Veterans Administration are attracting a very high quality of medical talent

Approximately 150 residents are now in training, and this number will be more than doubled before this issue of The Journal goes to press The Veterans Administration hopes to have 750 residents in training within four months All residencies will have the approval of the specialty boards before being offered

There are still vacancies in the Department of Medicine and Surgery of the Veterans Administration Applications are welcomed from two classes of physicians—those who are already well trained and well qualified and those who desire to become well trained and well qualified Great opportunities for teaching and research are offered the former group, and unexcelled opportunities for graduate training are offered the latter

MARQUETTE UNIVERSITY PHYSICIANS TO TAKE CHARGE OF VETERANS HOSPITAL AT WOOD, WIS

The Veterans' Hospital at Wood, Wis, recently became a university hospital of Marquette University School of Medicine, Milwaukee, after a conference of Veterans Administration heads with a committee headed by Dr Eben J Carey, dean of the school Under the plan, physicians now at Veterans' Hospital will continue in administrative positions, and specialists from Marquette University School of Medicine will be in full charge of the medical care of veterans

Taking part in the conference was Major Paul B Magnuson, former professor of surgery at Northwestern University Medical School, Chicago, new chief of research for the Veterans Administration, Washington D C, Lieut Col Lyle Baker, medical chief of staff at Hines Veterans' Hospital, Maywood, Ill, and Lieut Col Glenn Mullins, chief medical officer of the hospital at Wood

The committee consists of Dr Fred Madison, who will be in charge of medicine, Dr Carl W Eberbach, surgery, Dr Henry Olsen, obstetrics and gynecology, for women veterans, Dr Herman Schumm, orthopedics, Dr John Garvey, neuropsychiatry, and Dr Leander Van Hecke, pathology The consultants will serve half of each day at salaries up to $6,000 Consultants and residents will be appointed by the dean's committee with approval of the Washington office of the Veterans Administration

MISCELLANEOUS

HOSPITALS NEEDING INTERNS AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their house staff quota allotted by the Procurement and Assignment Service

CALIFORNIA

San Diego County General Hospital San Diego Capacity 727 admissions, 6 304 Dr H M Fine Superintendent (resident—tuberculosis discharged medical officer, May 15)

CONNECTICUT

Bristol Hospital, Bristol Capacity 180 admissions 4 414 Miss F L Sanborn R N, Superintendent (resident—mixed service)

INDIANA

Clinic Hospital, Bluffton Capacity 51, admissions 2 058 Dr Harold D Caylor (resident—mixed service)

Ball Memorial Hospital Muncie Capacity, 247, admissions 6 890 Miss Nellie G Brown, R N, Superintendent (interns July 1)

MINNESOTA

St Luke's Hospital Duluth Capacity 270 admissions 8 995 Mr James McNee Superintendent (resident—pathology)

NEBRASKA

Lincoln General Hospital Lincoln Capacity, 223, admissions 5 649 Mr Robert B Witham Administrator (3 interns 1 male 2 female, resident—mixed service)

NEW YORK

Goldwater Memorial Hospital New York City Capacity, 1,660, admissions, 1,505 Dr C G Scherf, Superintendent (2 residents—pathology, discharged medical officers July 1)

OHIO

Glenville Hospital Cleveland Capacity, 135 admissions 3 380 Mr Arthur B Harris Superintendent (resident—mixed service July 1)

St Elizabeth Hospital Dayton Capacity, 375, admissions, 9,126 Sister Devota Administrator (intern, residents—mixed service)

UNRRA NEWS

Artificial Limb Program in Liberated Countries

The United States Relief and Rehabilitation Administration Washington, D C, recently announced that thousands of persons in Europe and Asia who lost arms or legs as a result of the war will receive artificial limbs as a result of arrangements completed between UNRRA and the governments of five countries Under the arrangements the governments of these countries will set up plants to manufacture the limbs under government ownership and operation UNRRA will supply necessary component parts of machinery and equipment which must be obtained in the United States, and also some of the materials for the limbs, at least at the start of the operation UNRRA also will arrange for training workers in the government owned plants

The governments which already have asked UNRRA to aid in establishing their factories are those of Greece, Yugoslavia the Ukraine Byelorussia and Poland The Chinese government probably will make a similar arrangement

In addition, as part of its medical program UNRRA will provide emergency supplies of limbs manufactured in this country to persons in Greece before the Greek government can set up its plant

ASSIGNED TO SURGICAL CONSULTANTS DIVISION

Lieut Col Oscar P Hampton Jr University City Mo was recently assigned to the Surgical Consultants Division Orthopedics Branch Office of the Surgeon General Dr Hampton was recently awarded the Legion of Merit (The Journal, January 26, p 219)

Angelucci, Ralph J., Major, Vanderbilt Hosp., Nashville.
Busey, John F. Jr., Major, U. S. Vet. Hosp., Mountain Home.
Cardwell, Robert J., Capt., Nashville G. H., Nashville.
Carrier, Everett E., Major, 207 W. 5th Avenue, Fountain City.
DeGutierrez-Mahoney, Carlos G., Lt. Col., Vanderbilt U. Hosp., Nashville.

Texas

Ainsworth, William H., Capt., John Sealy Hospital, Galveston.
Dathe, Richard A., Lt. Col., 2703 Oak Lawn Ave., Dallas.
Hodges, Frank C., Major, 102 Oldham Lane, Abilene.
Lawrence, Buell A., Capt., 704 Dallas Ave., Houston.
Winborn, Claude De, Lt. Col., 1026 S. Beacon, Dallas.

Virginia

Ambler, John T. B., Capt., 371 Allison Ave. S.W., Roanoke.
Clary, Beverly B., 1st Lt., 2809 Hawthorne Ave., Richmond.
Dixon, Joseph M., Lt. Col., 1510 Franklin Rd., Roanoke.
Kuhnert, Thomas H., Capt., 819 Moore St., Bristol.
Oglesby, Forrest E., Major, Box 23, Oceana.
Trice, Ernest T., Lt. Col., 1701 Grove Avenue, Richmond.

Washington

Bowers, James M., Major, 3417 Shore Dr., Seattle.
Grover, Glenn G., Capt., 3354 E. Laurelhurst Drive, Seattle.
Lyon, Clarence L., Capt., 423 W. 24th Ave., Spokane.
Rickles, George A., Capt., Fort Steilacoom.

ORGANIZATION SECTION

ANNUAL CONFERENCE OF SECRETARIES AND EDITORS OF CONSTITUENT STATE MEDICAL ASSOCIATIONS

Dr. Creighton Barker, New Haven, Conn., Presiding

(Continued from page 652)

Friday, February 8—Afternoon

State Plans for Aid to Returning Medical Veterans

Major General George F. Lull, Associate General Manager, American Medical Association: I should like to read you a letter received here at headquarters. This letter is typical of many we receive from men in the service and from veterans. This is a little stronger, probably, than the average, but some of the letters are even stronger than this. This was written to the Editor of The Journal:

"We would like to know what the American Medical Association is doing for us who have risked our lives a thousand times that the rest of you might be smug and secure.

"I personally was with the famous 100th First Airborne Division for over two years, and as a qualified glider combat infantry physician I am lucky to be alive and not disabled.

"Most of my medical friends, many younger than myself, who played up trivial disabilities to dodge their responsibilities during the national emergency, have made enough money during our absence to retire or take it easy for the rest of their lives with the cream of the practice.

"What have they done for us besides pat us on the back, congratulate us on returning home alive and well? Nothing! What have the local, state and national medical societies done for us? We don't expect monetary returns, and although they inveigled us into the service with promises of an endowment system of some sort which would compensate us for our loss, no promises were kept. However, this was too much to expect of selfish human motives.

"Once and for all the barriers must be lifted if justice is to be done, and we know your medical trust has exerted powerful influence against us. Reconsider our case, or ten thousand of us shall fight you in federal courts with the last dime and breath we possess. There is no need for your dictatorial censorship. That is what we fought for and shall continue to fight for to our dying day!"

That is a letter received from a man who is angry, and he is going to take it out on somebody. While he is in the Army he thinks the Surgeon General and the American Medical Association are to blame; the nearer he comes to getting out the more blame he pushes on the American Medical Association. Neither of them in ninety-nine cases out of a hundred had anything to do with his particular situation.

One of the problems organized medicine has to face at present is this returning medical veteran. This problem faces our societies at the county, state and national levels. It is at the lower levels, however, where the greatest aid can be given to these men who left their practices to enter service in the armed forces.

Lack of housing, of suitable office space, and the inability to secure equipment, automobiles and clothing are problems that arise in many communities. I am a victim of that myself; my prewar clothes are such that they don't fit in certain places, and buying a suit of clothes now is just like when we used to buy a gallon of moonshine in the prohibition days: You have to have a friend who knows a fellow who has a suit, and in that way you get one. Housing is about as bad.

The inability to secure housing and office space is much greater in the urban than in the rural communities. It is up to medical organizations to aid these men. Many of these veterans gripe about having been forgotten men by their county, state and national organizations. This is not universal, however, and in many cases could not have been completely avoided. The time to render them service that would be appreciated is immediately on their return.

The American Medical Association established a Bureau of Information in September 1944. Its function in brief is as follows:

Medical officers contacting the Bureau for information regarding opportunities in certain states are furnished with complete listings of the areas in the states where there is need for a physician. Summary sheets giving the medical facilities and the physician aspects of the country are available for a particular area in which the doctor may be interested. For further information regarding the establishment of a practice in a certain area he is referred to the secretaries of the state and county medical societies. Specific inquiries regarding postwar education are referred to the Council on Medical Education and Hospitals, where a survey is made every six weeks to ascertain the number of vacancies available in approved hospitals for returning medical officers.

The Council is also continuing its efforts to establish additional high grade residency programs in hospitals that have not yet developed their educational services to the fullest capacity. All requests for information regarding medical education, licensure, relocation and benefits available to medical officers under the G. I. Bill of Rights are referred either to the Bureau of Legal Medicine and Legislation or to the Council on Medical Education and Hospitals. The same procedure is followed in interviews with the returning veterans who have visited headquarters in person.

All inquiries receive careful attention, and every effort is made to supply complete information to all medical officers. Since V-J day the Bureau of Information here has received each week about 565 letters from medical officers, and a weekly average of 110 physicians have come to the office for specific information in their adjustment to civil life.

In order to give this service to the returning veteran we must rely on the state and county societies to give us accurate statistics covering the medical facilities of every community. We must at all times, through the cooperation of the state and county medical societies, have a picture of the medical personnel in their areas and of the present and future needs for the adequate medical care of the community.

There is considerable difference between what happens at the state or the county level and what happens here in headquarters. As a rule the man who comes here is a man looking for a location or a residency or further education, and he has not decided himself just where he will settle or where he would like to settle. He is open minded about it. The man who comes to you has narrowed it down to the state level, and, as he goes on down the line, to the county level.

Under date of Jan. 3, 1946 the Bureau of Information requested all state medical societies to furnish them with detailed information as to their plans and those of their constituent societies for the returning veterans. To date twenty-seven societies out of the forty-nine have replied. These replies indicated the vast difference in the problems in different geographic areas; for instance, one Western state replied "The majority of the fifty-three physicians who left practice in .... State to enter the armed forces have by this time returned to their respective communities and again have taken up where they left off."

It would be foolish for that state to establish a big office or to publish bulletins of information, because there is no need of it. This is the exception, however, rather than the rule.

The problems in the various states vary greatly, owing to the distribution of population largely and to the requirements in the specific state. Some states reported that they have taken no steps to aid the returning physician. We discounted this as we know that if the returning physician goes to state headquarters or to the state secretary he will be given advice and all the information possible. Usually in those states the secretary has all the information at hand. He does not have to depend so much on the county societies. Although some of these states may be geographically large, the population is usually low.

I have selected a few replies and will quote them as examples. Many of the aids being cited in the examples quoted have also been extended to veterans by other state and county medical societies and are not original by any means, but they give a good cross section of the action taken.

The District of Columbia Medical Society was taken as an example of one whose membership comes from an entirely urban population, with no problems common to rural areas. I quote extensively from the secretary's report:

"We are endeavoring to obtain office space for physician veterans by every possible method. We have directed letters to the Board of Trade, the Real Estate Board, the Public Buildings Administration. We have conferred with owners of buildings and real estate men. We have issued statements to the press. The results have been fair. We did locate one six-story building which is being converted by the owner into a professional building.

"There are other prospects in the offing, but the situation generally is not good. We are seeking priorities for doctors, especially for automobiles. Wires have been sent to all automobile distributors in Washington requesting their cooperation. The response to date has been good. We bring the veterans up to date on new laws relative to licenses, narcotics and so on. We have published the return of service physicians in the newspapers. A list of them was published in the *Washington Post* a short time ago. Several veterans called on us stating that they had received calls thereafter.

"We give the veteran a six month subscription to our telephone exchange, the Medical Bureau. When we receive calls from patients who do not have a family doctor, they are shown preference. We have complete data on postgraduate courses offered by local medical schools, as well as pamphlets on postgraduate courses in other schools throughout the country. These are provided veterans on request."

In addition to the foregoing, the secretary personally counsels with veterans when they come home and come into the office. The secretary of the society has corresponded with its members during the war by sending them news letters at least every sixty days. As they are all located so close to the society's office, that is, in peacetime, most of them come to see the secretary on their return from service.

"I believe that one of the best things that can be done for returning medical veterans is to discuss in person their problems and give them advice. In this way, rather than by means of letters and bulletins which are valuable in themselves, it gives a personal touch, and the man is more appreciative of what is being done for him than if he simply reads it in a bulletin."

As an example of a state with many problems involving rural practice, I have selected the report from the secretary of Oklahoma. "The Oklahoma State Medical Association," quoting from his report, "has completed a comprehensive survey of the medical needs of the state, which was made by component county societies. They also have published a year book which gives the new doctor facts about the practice of medicine in the state and brings the returning practitioner up to date.

"Oklahoma has mailed to all service men of the state a letter telling them of the services available in the headquarters office should they desire to avail themselves of it. The office also acts as a clearing house for information concerning postgraduate and refresher training at the state university and medical schools located outside of the state. Several county medical societies have likewise set up committees to assist in the securing of office space and loan funds should veterans need ready cash. One county medical society has raised sufficient funds to guarantee office rent and equipment for its members if needed.

"The state medical society is sponsoring a continuing course in surgical diagnosis which all military officers on active duty and in government installations of the state are able to attend free. These courses are particularly well adapted to the returning veteran."

The secretary modestly added at the end "Obviously the foregoing is no greater nor lesser than all other state medical associations are doing" and calls attention to the fact that they operate largely on the basis of a rural area.

It was impossible to tabulate definitely just what each state was doing. However, some of the aids that have been extended varied from a remark submitted by one state, "We have no organization or definite program," to rather extensive and detailed programs submitted by other states. Obviously the report received from the state that had no definite program did not mean that the veterans would be given a cold shoulder should they ask for guidance or aid. It simply meant there was nothing organized and that the veteran would have to seek for himself.

Seven of the states replied that, although they were helping the veteran, they had no organized program. Several more stated that they extended a letter of welcome to the returning veterans as soon as they found out they were back. Ten of the states stressed the personal contact I have mentioned previously, and certain states have waived the dues for veterans for the first year after they return. Quite a few states have raised loan funds which are readily obtainable by the veteran. One county medical society sent in a copy of a large advertisement which had been placed in the county newspapers, giving the names of the returning service men in the county and those still in the service and advising patients to return to them when they needed medical care provided the specific doctor had opened his office.

Many county medical societies have Welcome Home dinners for returning veterans. Mention was made of the fact that in some places physicians had leased doctors' offices. These men in some places were being asked to vacate when the doctor returned and desired his office back. In many states the state medical associations' headquarters acted as a clearing house in most states for all medical information and got in touch with the veterans in many cases by phone, letters or by wire upon their return.

Out of the twenty seven replies received, twenty showed that a definite, active program was being carried out at the state and county levels, and I have no doubt that active programs are being carried out in many of the states from which no replies have been received.

Returning veterans are going to play an active part in organized medicine in the future. They have been in close contact with doctors from all parts of the country, in hospitals and camps. They have discussed with one another the various problems of organized medicine, and many of them have definite ideas as to what should and what should not be done.

We have received in the headquarters office quite a number of letters from men in the service who complain bitterly about what they have heard from men who have been separated and returned to practice. They resented the fact that some of the men considered nonessential in the community, and not available for military service, were now reaping the benefits of huge practices. From the tone of these letters these men have no grudge against the older men or against the men who had to remain at home on account of their essentiality. They complain, however, that there were some men who remained at home because of alleged essentiality. This of course is a matter of opinion only, but I know they have definite views on this subject and will express themselves vocally on their return.

I should like to call attention to one thing I have heard rumors about—not only rumors but talk—and that is in certain localities county societies are refusing memberships to doctors who come into the county—a flat refusal. Any doctor going into the county is refused membership in the county society. The one county I have in mind in particular was probably the most vocal county during the war, demanding that doctors be not taken, and that all residents in the county be deferred and every other man who was selected be deferred. Now I understand no one who was not there during the war or prior to the war will be allowed to join the county society. That is the story I have heard.

No doubt there is going to be quite a shift of physicians in the United States. This occurred after the last war and included all age groups. Many doctors make contacts in the Army which lead to partnership or membership in groups in places other than where they practiced prior to the war. A great load has been thrust on our hospitals and teaching institutions on account of the large number of veterans who desire either refresher courses or further training in some specialty. This will continue for several years, as many of them want two or three year courses, and the young men who entered the services during the last year or two have for the most part only a nine months internship. The bulk of these men will desire further training when they are released. The hospitals and colleges have done an excellent job in trying to absorb this huge load.

In closing I would like to say that any assistance you can render the veteran will repay your organization many times, as it starts the man out with a feeling of friendship and appreciation. This normally should be followed by an active interest in the organization.

DISCUSSION

Dr. Victor Johnson, Chicago: We have realized since the beginning of the war the responsibility that faces the Council on Medical Education and Hospitals in providing additional facilities for medical officers, particularly residencies. We sought to obtain as much sound information as we could so that we could employ the term "estimation" instead of "guessing," but much of it nevertheless was guessing. We tried to find out what medical officers would want in the way of additional training through questionnaires distributed to all the men in the armed forces, to some 63,000 of them. We obtained replies from 21,000 and we knew thereby, relatively objectively, what these 21,000 men said they wanted at the time they said it. There remained the guesswork of two kinds, How many men who said they wanted training would, on return, decide that after all they did not want it? Secondly, What about the 40,000-odd men who failed to reply to these questionnaires? What would they want? There is no way statistically, I am told by people who conduct polls, to make a reasonably good estimate on matters of that kind. We did the best guessing we could and arrived at the conclusion that about twice as many residency places would meet the probable needs as we had in the prewar days. A second guess had to be made, namely, When would the war end, particularly how long would be the period of time between V-E day and V-J day? We asked General Lull and other important persons who were well qualified to guess, and we arrived at this tentative estimate that perhaps around two years after V-E day we might expect that most of our medical officers would be discharged. We know now that in less than a year after V-E day most of the medical officers will be discharged. None of us regrets the rapid termination of the Asiatic phase, but it has made some of our estimates look much more like guesses.

Because of this rapid discharge of medical officers now, we have had to devise a number of procedures relatively quickly. Some of these have been mentioned. We have worked with the Procurement and Assignment Service and helped to induce them not to count veteran physicians on hospital quotas. A hospital with a quota of ten house officers could add five veterans without being penalized by the Procurement and Assignment Service. Furthermore, we have urged the discontinuation of the 9-9-9 program to the Procurement and Assignment Service, and that will be discontinued this spring. That is important because it means, as far as the veterans are concerned, that none of the recent graduates will be permitted more than a year of internship, none of the recent graduates therefore will occupy places which veterans might occupy, and consequently there will be freed around April 1 approximately 2,000 residencies for returning medical officers; there will be no more quotas at all after April 1. Also we have been working with the specialty boards on the temporary approval of residencies. In peacetime it took a long time to get a residency approved. The hospital would apply. When our inspector happened to be in that region of the country he would inspect the hospital. At the next meeting of the Council the application would be considered; it would then be referred to the specialty board, and at its next meeting it would be considered. Perhaps six or eight months, even a year, would elapse between application and final approval. That was all right in peacetime, but it is unsatisfactory at present. We are working with the boards on a scheme for temporary approval of hospitals which should reduce the time between application and final approval on a temporary basis to something like two weeks instead of several weeks or several months. Three of the specialty boards have already agreed to this plan, and we expect that most if not all the others will join us also.

Assistance will be given in meeting the needs of the returning medical officers in the training programs being developed, and in some cases under operation in the Army and in the Navy and the Veterans Administration hospitals. As a result of these efforts we feel that there will be available by April 1 four to five thousand residencies for returning medical officers. This was about the number we thought we would need provided demobilization extended over a two year period. This number many thought would meet the needs of all the officers who are desirous of training, but even if we knew the war would terminate as rapidly as it did, even if we knew that, I doubt whether we could expand our residency facilities beyond the present expansion or beyond the expansion as of April 1, 1946 without some diluting of the services, so that in the end we would have a net loss rather than a gain in medical education at that level. "Do we need as many specialists as it apparently seems we are going to have if the veterans get their way?" We have gone on the assumption that we ought to expand these educational facilities as fully as we can without diluting them to meet the needs of as many qualified veterans as possible. We do not look on this expansion program as an emergency affair entirely. We feel that in many ways our educational program has been greatly improved by this stimulus, because more and more hospitals are collaborating with one another in their residency programs; more and more hospitals are collaborating or associating themselves with medical schools in carrying out this program. I feel that there will result a stronger residency program after the war than we had before the war and that we shall have additional places available after the war, used now by veterans but available shortly to our Latin American colleagues, for example, who will be coming to this country in greatly increasing numbers for advance medical training.

SURPLUS PROPERTY

Mr. Robert C. Ayers, Director of the War Property Distribution of the Federal Security Administration: When the Surplus Property Act was passed, it was passed before V-E day. It has not been amended since that time. It has been implemented both pro and con by regulations. It has gone through three changes of administration. Section 13 of the act provides that surplus property, useful for education and health, shall be sold or leased to education and health institutions and that in fixing the sale or lease price the benefit that has accrued to the United States or which will accrue to the United States may be taken into consideration. On Nov. 6, 1945 regulation 14 was passed to implement section 13 of the act. Mr. Symington, who was then the surplus property administrator, picked the Federal Security Agency as the certifying agency for health, education and welfare institutions and also fixed a 40 per cent discount from fair value as the purchase price of material for those two types of institutions. On the welfare side, then, they still buy at fair value. Today there are four categories of priorities within that act. The first and the top priority on all types of property is the federal government itself. The second priority goes to the state and local government; the third priority goes to veterans, and the fourth priority goes to nonprofit institutions. The returning veteran does not have at the present time much of a break as far as surplus property is concerned. He comes in now under the third priority. Almost everything up to now is what is termed in short supply. While the Army says that the floodgates of surplus property are now open and that the flow of it is going forward, experience teaches and shows us that when the federal government has satisfied its needs, and when the state and local governments have satisfied their needs, the veteran takes just about what is left over. There is at this time pending in the Congress of the United States a bill to make veterans the second priority, subject only to the federal government. While I am no forecaster at all of what Congress will do, my guess is that it will pass and make the veteran the No. 2 priority.

I suppose the reason the Federal Security Agency was asked to assume the responsibility of certifications on health, education and welfare institutions is that within the Federal Security Agency there are three constituent units: the U. S. Public Health Service, the United States Office of Education and the Social Security Board, which deal directly with the state departments of public welfare throughout the length and breadth of the nation. Therefore we have set up within the Public Health Service the Division of Surplus Property Utilization, and within the Office of Education a similar division, and within the Social Security Board a similar division. At the outset there was a Surplus Property Board, and the Department of Commerce was the main disposal agency; that lasted but a short time. Congress amended the act and made a single administrator, and then the Department of Commerce got tired of being the disposal agency and it was transferred to the Reconstruction Finance Corporation. Then Mr. Symington resigned and became an Undersecretary of War, and the RFC got tired of being a disposal agency; so the War Assets Corporation was formed, and there came into full bloom on February 1 a single agency, so to speak. General Gregory was appointed the chairman of the board of the War Assets Corporation and also the acting administrator of surplus property. At the same time the President by executive order transferred the Surplus Property Administration over to the office of the chairman of that board. Under his reorganization powers he is setting up on March 25 a single War Assets Agency, the reason being to try to bring it all, both the policy making feature and the actual operation feature, under one man who promulgates the policy.

Today we have in each of the eleven War Assets Consumers Goods offices a sanitary engineer on the public health side and a medical man. Today both of these men in each office are doctors. If you go down to 209 South La Salle Street you will find our people there. A health institution, be it a state, a local government or a nonprofit hospital health agency of that kind, when it makes its application and places its order for surplus property of any kind that it may need (and I have yet to see any surplus property that a hospital and health institution cannot use in some form or other) that application goes directly to the disposal agency where our people are located, and there the application is processed by our people. It is either approved or modified as the case may be, and the order is filled from the available property there. We started out with what appeared to be a beautiful plan. We thought we could stockpile, that we could build up some reserves and make a comprehensive survey of the hospital needs throughout the country and put this material into the places where the need was the greatest. But the pressure (and I am not saying it should not be) to get the property out into the channels where it is needed made us streamline our procedure to that extent. Undoubtedly we will find more streamlining necessary, with a similar plan for the educational field and for the welfare field. However, the welfare institutions as such are not entitled to the 40 per cent discount.

Before the Smaller Plants Corporation was sent out of existence, through the efforts of the Public Health Service at the central office in Washington an attempt was made to put a doctor, either a veteran or a nonveteran, in the class of a public health institution. I was one who supported that. The Smaller War Plants Corporation said no, that the Surplus Property Act meant an institution and not a person. It seemed to a group of us that one could certainly say that a doctor or a dentist was an institution, but we didn't get very far with it. We thought they were beginning to yield, and then finally with pressure from the veterans we were about to point to where we thought we were going to put it over as far as the veterans were concerned and then let the veterans buy under their priority with the Smaller War Plants Corporation, which would give them priority No. 1. But in the meantime the Smaller War Plants Corporation went out of existence, and we are right back with the veterans having a No. 3 priority and not being classed as an institution. There are many proposed amendments and many pressure groups that would like to see the veterans have a No. 2 priority, and in the case of a doctor and dentist they would be given the 40 per cent discount or whatever other discount may later on come about.

FURTHER DISCUSSION

DR. HENRY A. DAVIDSON, Trenton, N. J.: Would Mr. Ayers outline for us briefly and concretely just how a doctor veteran who has just taken off the cotton and put on blue serge, who needs a tuning fork which he cannot buy, goes about getting things? Where does he take himself, to what place, and what does he do to get the tuning fork from the army or navy surplus?

MR. AYERS: There are two methods the veteran doctor may employ: He takes his discharge papers or his terminal leave papers, or proof of the fact that he is a veteran, to the Smaller War Plants Corporation or to a disposal agency of the War Assets Corporation. I rather imagine all of the secretaries have the locations of those offices; if not, I will see that you are furnished with it. He is there granted a certificate stating that he has preference rights as a veteran to buy surplus government property, and it lists the kind and quantity of such property he wants to buy. Then he goes to the disposal agency; that is the War Assets Corporation, and after March 25 it will be the War Assets Administration. There are eleven of them throughout the country on consumer goods. There are some twenty-two of them today on capital goods. The thinking topside in the War Assets Corporation is that there will be one to every state. I guard my language there because today that is the thinking. I believe the thinking will get into full bloom, because an estimate was taken the other day of the amount of surplus property disposed of today and the amount estimated on hand, and at the rate they are going at the present time it would be some twenty-six and a half years before they could dispose of the surplus property. One other essential is to get on the mailing list of the War Assets Corporation. In that way you will receive listings of what is coming out, and where it is to be disposed of.

DR. DAVIDSON: How do we get on that?

MR. AYERS: By writing the War Assets Corporation.

CHAIRMAN BARKER: Dr. Fishbein, weren't those addresses published in THE JOURNAL?

DR. FISHBEIN: Within the last week, and also the letter telling them what their rights are.

MR. AYERS: Fine. The certificate from the Smaller War Plants Corporation gives you in effect a search warrant to go out and find the property and, if you can find it, get it.

DR. MICHAEL A. TIGHE, Lowell, Mass.: We in Massachusetts had an information bureau set up before the war was over, in anticipation of getting the thing into operation so that when the war did close we would have a good functioning outlet. We think we have a fairly good functioning outlet. Our medical society has established what we might call a series of circuit riders, who go out through the state visiting each section of the state—at least the plan for this year is to have them visit each section of the state—three times, spending two days in each section. The men who are participating in the instruction are the best men in our state, and in addition to that there will be in Boston, beginning next week and running until May, two exercises a week which will start at 4 o'clock in the afternoon, with a recess for dinner and then continuing in the evening. There again the leading medical men in our state are participating. Our three medical schools have established refresher courses of six months' length. All of this material is on file in our information bureau. One thing we seem to have had the most trouble with has been the location of men coming back from the service. We are an urban state, of course, and there is no great scarcity of doctors in our state. We have had to be extremely careful not to recommend an individual to go into a community which for the moment might be short of doctors and have him take the place of some veteran who shortly will return. Our second really serious problem was the matter touched on by Mr. Ayers. I have boys who have never practiced, who went directly from their internship into the Army. There are a lot of them. They come to my office after they have been to the information bureau, and they tell me their troubles, about their difficulty in getting an office, and so on. We can't do too much for them in that respect, but after a while they come back and say "I have found an office in the location in which I expect to practice. I can't find a darned thing to put in it. I have made the rounds of all these outfits that are supplying doctors' equipment." I had a boy say to me last week that they wanted $250 for a desk, $300 for an examining table and $75 for a sterilizer. "Where am I going to get all that money?" he asked. These boys say they were given to understand that the government has a lot of surplus material, and "when is it going to be opened up to the veteran doctor? We think we should have an opportunity to purchase some of it. Why can't we do so?" Some of the men have talked plainly to me. They have talked to me along the lines of the letter that was read by General Lull. They say "Are the commercial houses behind the movement to prevent this surplus property from being distributed?" I don't believe that is so, but that is what these boys are thinking. They have pressing needs; they have found an office, a location, but nothing to put in it.

Mr. Ayres: There are a number of things to prevent that boy from outfitting himself. For instance, here is a catalogue in my hand showing surgical instruments and other things Dr. Tighe was talking about. This catalogue gives the code numbers, the prices and so on. It is issued from the regional office of the Cincinnati War Assets Corporation. Apparently there is a large depot of that sort of material at Cincinnati. There is another large depot of the material that doctors and hospitals need at Denver. It is not scattered around over the nation. For instance, running my eyes down this page, I see sterilizers and things a doctor needs. The sale of that equipment closes to the priority group on February 13, and you have about fifteen days from the time it is opened to the veteran or to the doctor to place your order and get it. In many instances the veteran doctor does not want to buy it until he can inspect it.

Dr. Holman Taylor, Fort Worth, Texas: A doctor in Texas wanted to buy one of the hospitals. I couldn't find out to whom we should direct an inquiry as to the cost of that hospital; one day while I was trying to find out about it, my telephone rang and an agent of the Surplus Property people, right there in Forth Worth, rang me up to know about a doctor who wanted to buy that same property. The Brinkley outfit wanted to buy it. I think every state ought to have a list of people from whom they could find out about these things.

Mr. Ayers: In each one of these Consumer Goods offices there are two persons from the Public Health Service. One is a doctor and the other is a sanitary engineer. If you can make contact with these men I am sure they will see that you get on the mailing list.

Dr. R. B. Anderson, Fort Worth, Texas: I am not quite clear about this. If some information was published in The Journal a week ago and if it came from the same source that we got some from about the same time, it has already been changed.

Dr. Fishbein: I have been working with this question of surplus property disposal for about eight months. We were first called to a meeting in Washington, which Dr. Irons and I attended as representatives of the Board of Trustees, to consider the whole question as to how the Surplus Properties Act could be best administered for the advancement of the public health and for aiding physician veterans in getting back into practice. That conference met for a full day; some fine principles were agreed to by everybody concerned. Among other things it was agreed by the group in Washington who were in authority at the time that a complete set of office equipment might be assembled which would be leased to a returning veteran for $1 a year in case he went to an area in need of a physician, and that the U. S. Public Health Service would be the certifying agency to assure the government that that area was in need of a physician and that he was a qualified physician to move into such an area. After that meeting we heard nothing further about the matter for some time because Washington was in the process of removing one group and putting in an individual, as Mr. Ayers has already mentioned. After this the entire procedure changed and everything that was there decided on was canceled. Since that time, as Mr. Ayers has said, the procedure has changed almost as rapidly as a new procedure is developed. About ten days ago we received from the Surplus Property Administration the announcement of the offices which would have available the lists of property for disposal, and the regulations under which such property would be made available to nonprofit medical institutions and to physician veterans. That was the statement which we printed promptly in The Journal. It reached us on a Monday morning and we went to press that afternoon. On the next day a representative of the U. S. Public Health Service called on us to say that he was now in charge of this matter and that he was proposing to write for the benefit of the medical profession a communication which would give all the details as to how surplus property would be made available to physicians.

I said "We are printing that this week."

He said "I would like to see it."

I showed it to him and he said "I never heard of it. This must have come out since I left Washington."

"When did you leave Washington?"

"Day before yesterday."

It is rather futile to comment here on the chaos and confusion that have been associated with the disposal of surplus property. I think everybody in the country knows that it has not been well organized, that there has been no consistent policy, that there has been constant changing from one group to another in control. Obviously if the federal government were efficient in this matter and were really anxious to see to it that rural areas not at present served adequately by physicians could be served, they would try to do something definite and positive toward making office equipment and cars available to physicians who are willing to go into rural areas to practice. That was the intent of the law. That section of the law was written after innumerable conferences with the American Medical Association, the American Public Health Association, the American Hospital Association and every medical and welfare organization in the United States. That section of the law was designed to encourage a movement to send qualified physicians into rural areas by making it relatively easy for them to go into such areas and practice. The purpose and intent of the law as developed by Congress have been completely defeated by red tape.

Mr. Bryan: I was especially interested in what Dr. Fishbein had to say, because our experience in New York has been exactly along the same line. In fact, to save the time of the veterans we no longer suggest that they go to see the Small War Plants Corporation or any of its offsprings, because they would only be wasting their time. They have easily 16,000 applicants for every surplus car available. It has seemed to us that there is now just as much justification for the government to instal a system of car rationing, such as was in effect during the war, as there ever was during the war. Physicians need cars, and certainly, the government rates being what they are, we cannot expect that all the needs of the country can be taken care of adequately soon. I was asked by our veterans' group to raise this question here, if possible, and to inquire what the sense of this group might be toward proposing, through whatever means may be necessary, to the federal government that a system of car rationing be reestablished with priorities along the same lines as were granted during the war.

Dr. George Kosmak, New York: We do not get specific information about surplus property. The *New York State Journal of Medicine* has a very large circulation, and the only thing we can do is to reprint the information that has been contained in The Journal of the American Medical Association. Of course we are glad to do so. It seems to me that if all the editors of state journals could be supplied with this information it would do a great deal of good. I know that in our own state the people don't know where to go to get it.

Dr. Graham, Oklahoma: I should like to ask if we could have a little bit more description of the various items rather than simply the serial number. Many of the men will say "Here is a sterilizer, serial 00324. Who makes it?" If they do not have a medical supply catalogue they can't answer that question. If a better description could be given of the product it would save the men a lot of time. For instance, sometimes they are not interested in x-ray machines except those of a certain particular brand.

Mr. Ayers: That same complaint has been voiced before. In the listing that I have in my hand it shows the manufacturer's name. This is the first such listing I have seen. What that will do to help I am sure I don't know, but apparently that complaint has come in sufficiently strongly to get them to put it on the listing.

Mr. H. T. Sethman, Denver: I have a question for Dr. Johnson. Naturally, the Council on Medical Education and Hospitals, and hospitals subscribing to its policies, are endeavoring to raise standards of practice. However, during the war years a number of hospitals have changed their staff rules and they now admit to practice in those hospitals only men who are certified by the appropriate American boards. Men are now returning from service in the armed forces who are not yet certified but who may have been in the preparatory stages of getting certification at the time they went into service. These men are told that they can no longer bring patients into that hospital and that they must no longer consider themselves members of the staff. Several veteran physicians are quite wrought up about it, some even distinctly profane, and some are threatening court action under the G. I. Bill of Rights. Has the Council on Medical Education and Hospitals considered this problem, has it established a policy, and what is that policy?

Dr. Victor Johnson: The Council is aware of such situations in a number of parts of the country. Our attitude, however, has been that all we can prescribe for an approved hospital is that the staff be competent. Until the G. I. bill went into effect with the provisions to which you refer, the courts repeatedly decided that it is within the right of a hospital itself to determine who shall be on its staff. Before this particular problem arose relative problems had been presented to us before the war about staff appointments and discrimination against one or another group or individuals, and that has been left pretty largely as a local problem in which we are more or less powerless to interfere because of the fact that hospitals have the right, under the law, to appoint whomever they wish on their staffs. I think it would be very difficult for any central agency to do any more than to determine whether the staff is competent to carry on the work of the hospital. The question is broader than merely hospital appointments. It extends to memberships in county medical societies, where in certain areas of the United States men simply cannot get in even though the area is badly in need of a physician. The answer is that we are aware of the problem but we are not certain how it can be solved.

Medical Service for Veterans

Colonel James C. Harding, Director, Outpatient Service, Veterans Administration: This paper appeared in The Journal, February 16, page 415.

DISCUSSION

Dr. L. Fernald Foster, Secretary, Michigan State Medical Society, Lansing: I hoped that today I might be able to present some data as to the success of the plan, but because of difficulties in the provision of forms and in view of the fact that the Veterans Administration is moving from Dearborn to Detroit there has been a delay. The first cases are going through the Michigan Medical Service offices today. It was obvious that, having an active, well established medical service plan was the first factor, and with that was the fact that it had to be a solvent corporation. Under the plan of Michigan it is possible that it will be necessary for the plan to make advances in funds, particularly if the load gets heavy, and that will be a sizable amount of money. In that event it is necessary that the plan be solvent to the point where it can provide that advance. Fortunately the Michigan Medical Service plan is just that. The second factor which I believe facilitated the execution of this contract was the development and adoption of a uniform fee schedule for governmental agencies. I have here a few of the fee schedules. This fee schedule is called "the Michigan uniform fee schedule for governmental agencies."

In the depths of the last depression the traditional altruism of the medical profession was apparent. Physicians agreed to do work for agencies of government, particularly in the indigent categories, for what was recognized as cost. I believe we were told at that time that about 50 per cent of the regular schedule represented the cost of rendering medical care. Our council, with a considerable degree of vision, some time ago recognized the fact that possibly within the next five or ten years we could visualize a large segment of our people, and representing a similar segment of private practice, as falling into some governmental category. It has even been said that the veterans themselves, some twelve million, let us say, might develop in the next ten years, with their dependents, into government wards. If and when such dependents should become government wards this would develop a group of some forty or fifty million people. If that many people fell into some governmental category it was perfectly obvious that no sound economics would stand for you and me and any one else rendering care to one third of the population on the basis of the cost of production. Some time ago, anticipating this, our council appointed a committee to study the development of a uniform fee schedule for governmental agencies, not only indigent groups, but any governmental groups, such as the veterans' group, which is certainly not an indigent group. This committee developed a schedule from a survey of county medical society fee schedules from consultation with specialty groups throughout the state, from consultation with hospital staffs and from every conceivable angle from which it could determine a fee schedule. It surveyed some 35,000 items and has developed this fee schedule, which contains 500 units of service representing the usual services rendered.

The philosophy behind this uniform fee schedule for governmental agencies is simply this: It was recognized that the laborer is worthy of his hire and that medical service should and must have an intrinsic value of some kind, and the question was developed in our mind particularly by one of our state officials, who said that if the state of Michigan, for instance, chose to buy a ton and a half truck, all it had to do was to look into a price list and it could find therein some semblance of the value of a ton and a half truck; if it chose to use it at the county poorhouse it didn't get the truck for half price but paid the same price for it whether it was used at the county poorhouse or at the University of Michigan. From that suggestion we realized that to some lay people there was confusion from the fact that there was such a disparity between the value of medical services; in other words, this official said that in a state with eighty-three counties, such as we have, and fifty-five component county medical societies, there were just that many price lists, so to speak, when one chose to buy medical service, and the disparity between it ran from $16.50 for major surgery in one county to $62.50 in another county for indigent categories; so there must be something wrong, that medical service could not vary that much in its value. We believed there should be evolved a minimal fee schedule, based somewhat on the intrinsic value of the commodity, that could be rendered to any agency of government, from the county, state and national levels, and that fee schedule was developed and adopted by the house of delegates and was already in effect at the time the veterans' problem arose. This uniform fee schedule at present is being presented by county medical societies to boards of supervisors, to state agencies of government, and will be offered to any other national agency that has a category for whom it desires to purchase services. Already the Michigan Crippled Children's Commission has adopted this schedule in principle, limited only by statutes, which in the present law limits them to a top level on certain procedures, and at the next session of the legislature it is contemplated that changes will be made in the statutes so that they can adopt this in toto.

The social welfare commission of the state of Michigan is now considering this schedule, and has told us that its adoption looks hopeful. If you look at this schedule you will find that it is a fine schedule of general practice. You will find that in a state such as ours, which varies tremendously in its geographic layout, it is even higher than the private practice schedule in some of the small counties, but by and large it is an average which we believe represents to a certain extent the minimal value of medical care, and that it should be offered to every agency of government irrespective of whether the category is an indigent group or whether it is a group such as the veterans. We believe it is not a question of who gets the service as to what they pay; it is a question of somebody going to have to pay for it. If they are government wards, the value should not be lowered because of that fact Fortunately our Medical Service plan is the Michigan State Medical Society. Its corporate body is the house of delegates. Therefore a contract that has been developed with Michigan Medical Service is a contract with the practitioners of the state of Michigan. We believe, therefore, that the integration of this responsibility from Michigan Medical Service through the house of delegates down to the individual doctor places on him a tremendous responsibility for the execution of this contract. We believe the successful conduct of this contract is going to do one thing to which we are all pointing as an objective, and that is to prove that a governmental agency can utilize a voluntary plan in private enterprise and that it is not necessary to set up a great bureaucracy. We are impressing on the individual doctor down in the smallest hamlet of the state that this service to the veteran must be rendered and that it must be good; that he has to render it with the same efficiency he would to his regular clientele; that it has to be given cheerfully, efficiently and in a sufficient quantity such as the needs demand.

DISCUSSION

Dr. Stanley B. Weld, Hartford, Conn: I want to ask Colonel Harding a question, if I may. He mentioned the chief medical officer as being the one able to authorize the care of the veteran. I did not quite understand where the chief medical officer is Is he in the hospital or in the Veterans Administration?

Colonel Harding: The chief medical officer would be the chief medical officer of a regional office, that is, having the administrative job. However, he can delegate it all the way down the line to any physician in any subregional office or any place along the line from the regional office

Dr. Weld: In view of the statement Dr. Foster made about the American Legion and the Advisory Committee of Physicians, I wish General Lull would give us what information he has on the Advisory Committee for the American Legion.

General Lull: The Advisory Committee was appointed by Mr. Siberling. We were told that we would make recommendations to the commander for the use of the executive committee of the American Legion that had any bearing on health. We could make these recommendations to the national commander for the use of the executive committee. This committee was asked to make a recommendation about the Veterans Administration bill, which we did Dr. Stroud was interested in starting something for the prevention of rheumatic heart disease, so we asked the executive committee to give us a grant and to pay the grant to the American Heart Association for the study of rheumatic heart disease in children, as something that would be backed by the American Legion. The central committee asked the chairman of the Rehabilitation Committee in Washington to prepare letters for the commander's signature to send to all state commanders, requesting that the state commander appoint a medical officer on his staff to whom he could turn for advice, and in addition each state commander was to request that a surgeon be appointed on every legion post. We stressed the fact that these men should not be simply job holders but should be men in the community who were looked up to as physicians. We thought that in this way we could probably be of some benefit. We have had replies from most of the states saying that they have appointed some physician as the state surgeon. We checked up on these men and for the most part they are good men. We did not check as far down as the posts. We left that up to the state.

Chairman Barker: You are properly guarded in your remarks, General Lull, because Dr. Weld is the surgeon to the American Legion in the state of Connecticut. He is a job holder and a respected physician.

Dr. Wingate M. Johnson, Winston-Salem, N. C.: The executive committee of the North Carolina State Medical Society, meeting January 27, voted to accept the contract Michigan has with the Veterans Administration, to be administered by the Hospital Saving Association (that is the Blue Cross), which was the first Blue Cross plan of the country sponsored by a state medical society.

Mr. Graham (Oklahoma): In Oklahoma recently I had an opportunity to speak to Mr. Lundquist, head of the Veterans Administration. Subsequently I talked to Major P. B. Smith, and I was rather startled to find that they knew very little about this plan that had been proposed some months ago by General Hawley. They have given us their most hearty cooperation, and we will go further as soon as we return from this meeting. The only reason why I make this comment is that I wonder how many other state medical societies who perhaps in the immediate future are going into the investigation of like plans are likely to run into that same situation with local veterans' administrators.

Colonel Harding: We purposely have not disseminated any of this news as yet because it is a new idea and it has a lot of kinks to it. Now that we have two or three concrete types of plans, it is our intention to disseminate this and to put it through our branch offices, these thirteen area offices that are now being organized. We have a deputy administrator in each one of them, and I think we have a deputy chief medical officer in each one of them. I have been handling it myself, and when you realize that there are forty-eight states it takes me an awfully long time to get through.

(To be continued)

Coming Medical Meetings

Aero Medical Association, Chicago, April 7-9 Dr. David S. Brachman, 1016 Dime Building, Detroit 26, Secretary.

Alabama, Medical Association of the State of, Birmingham, April 16-18. Dr Douglas L. Cannon, 519 Dexter Ave, Montgomery 4, Secretary.

American Association of Anatomists, Cleveland, April 4-6. Dr Eliot R. Clark, University of Pennsylvania School of Medicine, Philadelphia 4, Secretary.

American Pediatric Society, Skytop, Pa, May 1-3. Dr. Hugh McCulloch, 325 N. Euclid Ave, St. Louis 8, Secretary.

American Society for Research in Psychosomatic Problems, New York, May 11-12. Dr. Edwin G. Zabriskie, 714 Madison Ave, New York 21, Secretary.

American Surgical Association, Hot Springs, Va, April 2-4 Dr. Warfield M Firor, Johns Hopkins Hospital, Baltimore 5, Secretary.

Arizona State Medical Association, Phoenix, May 2-3. Dr. Frank J Milloy, 112 N. Central Ave, Phoenix, Secretary.

Arkansas Medical Society, Little Rock, April 14-15. Dr. W. R. Brooksher, 602 Garrison Ave, Fort Smith, Secretary.

California Medical Association, Los Angeles, May 7-10. Dr George H. Kress, 450 Sutter St., San Francisco 8, Secretary.

Central States Dermatological Society, Detroit, April 27. Dr. Clarence E Reyner, Henry Ford Hospital, Detroit, Secretary.

Connecticut State Medical Society, Hartford, May 1-3. Dr. Creighton Barker, 258 Church St, New Haven 10, Secretary.

Dallas Southern Clinical Society, Dallas, Texas, March 18-21. Dr. John G. Young, 1719 Pacific Avenue, Dallas 1, Director of Clinics

Florida Medical Association, Jacksonville, April 22-24. Dr. Robert B. McIver, P. O Box 1018, Jacksonville, Secretary.

Georgia, Medical Association of, Macon, May 7-10 Dr. Edgar D. Shanks, 478 Peachtree St, N.E, Atlanta, Secretary.

Iowa State Medical Society, Des Moines, April 17-19. Dr. John C. Parsons, 406 Sixth Ave., Des Moines 9, Secretary.

Kansas Medical Society, Wichita, April 22-25. Dr. F. R. Croson, 112 W. Sixth St, Topeka, Secretary.

Louisiana State Medical Society, Alexandria, May 6-8 Dr. P. T. Talbot, 1430 Tulane Ave., New Orleans 13, Secretary.

Maryland, Medical and Chirurgical Faculty of, Baltimore, April 23-24. Dr. W. Houston Toulson, 1211 Cathedral St, Baltimore 29, Secretary.

Medical Library Association, New Haven, Conn, March 25-27. Miss Frida Pliefke, 2000 Medical Arts Bldg, Minneapolis 2, Secretary.

Missouri State Medical Association, St Louis, March 24-26 Dr. Ralph L Thompson, 634 N. Grand Blvd, St. Louis 3, Secretary.

Nebraska State Medical Association, Lincoln, May 6-9. Dr. R. B. Adams, 416 Federal Securities Bldg., Lincoln 8, Secretary.

New Orleans Graduate Medical Assembly, New Orleans, April 1-4. Dr. Joseph S D'Antoni, 1430 Tulane Ave, New Orleans 13, Secretary.

New York, Medical Society of the State of, New York, April 29-May 3. Dr. Walter P. Anderton, 292 Madison Ave., New York 17, Secretary

North Carolina, Medical Society of the State of, Pinehurst, May 1-3. Dr. Roscoe D McMillan, P. O. Box 232, Red Springs, Secretary.

Ohio State Medical Association, Columbus, May 7-9. Mr. Charles S Nelson, 79 E. State St, Columbus, Executive Secretary.

Postgraduate Institute of the Philadelphia County Medical Society, Philadelphia, April 9-12. Dr. George P. Muller, 301 S. 21st St, Philadelphia, Director.

South Carolina Medical Association, Greenville, April 30-May 2. Dr. Julian P. Price, 105 W. Cheves St, Florence, Secretary.

Tennessee State Medical Association, Knoxville, April 9-11. Dr. W. M. Hardy, 706 Church Street, Nashville, Secretary.

Texas, State Medical Association of, Galveston, May 6-9. Dr. Holman Taylor, 1404 W. El Paso St., Fort Worth 3, Secretary.

Washington Letter

(From a Special Correspondent)

March 11, 1946.

Lack of Psychiatrists Called "Frightening"

Capt. Francis Braceland, head of the Navy's neuropsychiatric division, informed the Senate subcommittee considering the Pepper bill, which would set up and finance a National Neuropsychiatric Institute in Washington, that "a considerable block of America's civil population does not enjoy mental health." Leading army and civilian psychiatrists testified that there is a "frightening" lack of trained psychiatrists everywhere. Surg. Gen. Thomas Parran of the U. S. Public Health Service also testified in support of the bill. Dr. Lawrence Kuble, psychiatrist consultant to the Office of Scientific Research and Development, opposed the Pepper measure because he said it is inadequate, "like shooting at rocket bombs with a peashooter."

District Antivivisection Bill Losing Support

The Lemke bill to ban vivisection in the District of Columbia is making little headway. Federal Security Administrator Watson B. Miller has asked that the legislation forbidding medical research on dogs here be killed by the House District Committee. In a letter to Chairman John McMillan, Democrat of South Carolina, Mr. Miller warned that the measure would provide a precedent for antivivisectionists that would "seriously deter medical progress" elsewhere in the United States. He added that medical research on living animals has been invaluable in the search for benefits to man's life and health.

Opposition to Military Domination of Science

Dr. Edward U. Condon, director of the National Bureau of Standards, said here in a speech that "science simply cannot go forward under military domination," imposed because of the atom bomb. Simultaneously a fresh drive opened for enactment of the May bill on atomic energy policy in Congress. Among opponents was Representative Holified, Democrat of California, who issued a statement that "the current Canadian-Russian spy scare hysteria" did not afford sufficient grounds to "rejuvenate" atom legislation proposed by Chairman May, Democrat of Kentucky, of the House Military Affairs Committee.

Herbert Hoover to Survey European Food Needs

President Truman has appointed former President Herbert Hoover honorary chairman of a Famine Emergency Committee. Mr. Hoover will fly to Europe on March 15 along with Dr. F. R. Fitzgerald, food allocations officer of the Agriculture Department, and others, to check food requisitions submitted by various countries. Mr. Hoover carried out vast foreign relief programs in Europe after the war of 1914-1918. The United States will endeavor to supply food to war torn areas of Asia and Europe through economies effected by the President's voluntary food conservation program.

Hawley Puts Veterans Hospital on Twenty-Four Hour Day

Acting on complaints that medical care had been denied veterans "after business hours," Dr. Paul R. Hawley, chief medical director for the Veterans Administration, has ordered all veteran hospitals to maintain twenty-four hour medical service. The agency has launched a program to speed up repairs on veterans' artificial limbs.

Funds Asked to Modernize Bureau of Standards

President Truman has asked Congress for a million dollars to modernize the National Bureau of Standards. Acting Budget Director Paul H. Appleby said the present plant is in such bad repair that testing and research work cannot be conducted efficiently.

Suggestion that Doctors Instead of Goats Be Used in Atom Bomb Test

Representative William Lemke, Republican of Indiana, sponsor of the District antivivisection bill, was suggested by several of his fellow Congressmen, according to newspaper reports, as a possible candidate to substitute for goats in the forthcoming Navy atom bomb tests. The Southern Dairy Goat Owners and Breeders Association had protested the use of goats and suggested that Congressmen be used instead. Congressmen declined the honor but said that Mr. Lemke, as the leading animal lover in the House, might accept. "I'm pretty busy now," he is reported to have said. "Why don't they send some of those doctors who always want to cut up dogs?" he said. "This is their chance to see personally just how a living being reacts to this sort of thing." As an afterthought he told his interviewer that newspapermen should be used instead.

Outbreak of Q Fever Among Bethesda Research Workers

An outbreak of Q fever occurred among 26 laboratory workers of the Bethesda National Institute of Health. Dr. Charles Armstrong, chief of the contagious disease division of the National Institute of Health, said that they became infected by breathing the air in the building where Q fever research was being conducted. Those actually working on the disease apparently had developed immunity, because they stayed well. Washingtonians were told that there was no danger of an epidemic.

Treatment of Leprosy in Brazilian Colonies

Mrs. Dena Eunice Weaver of Rio de Janeiro, president of the Brazilian Federation of Societies for the Assistance of Lepers, is in Washington on a five months visit to the United States at the invitation of the Office of Inter-American Affairs. She will study operation and fund raising methods of such agencies as the National Tuberculosis Association and the National Foundation for Infantile Paralysis. She stated that her federation is now treating 17,000 leprous patients in thirty-six colonies in Brazil, which has an estimated 30,000.

Senate Approval of School Lunch Program

The Senate has passed a bill authorizing the federal government to contribute $100,000,000 annually to state operated free school lunch programs for needy children. The bill has been returned to the House, which approved a bill calling for just half this total last week. The Senate also authorized a maximum of $15,000,000 to assist states in providing lunch room facilities and nutrition education programs. This had been cut out of the House bill. An effort is now being made to create a compromise measure.

Army-Navy Merger Bill Redrafted

A revised Army-Navy merger bill providing for a single department of national defense under one secretary, but giving autonomy to the Army, Navy and Air Forces, has been completed by a Senate Military Affairs subcommittee. It will probably be returned to the full committee this week. The Navy is said to be still bitterly opposed to a merger. Any legislation adopted would naturally affect the medical departments of the armed services.

More Food, Medical Care, Urged for World's Children

Miss Katharine F. Lenroot, head of the Children's Bureau, United States Department of Labor, told the Congressional Club that 140 million persons in European countries are now living on 2,000 calories and another 100 million exist on 1,500 or less. Telling of her recent tour of Europe, she urged better food, and medical care for all children in the world. She warned that undernourished, ill clad children will not have the energy and stamina to build a permanent peace.

Benzene Hexachloride, Powerful Insecticide

Benzene hexachloride, an insecticide said to be seven times as effective against flies as DDT, has been described to Congress. The insecticide was disclosed to the House Appropriations Committee during hearings on the 1947 Agriculture Department Supply bill, which has gone to the House floor. The chemical is said to be effective against many insects not bothered by DDT and is extremely toxic to bees.

Medical Scientists to Observe Atom Bomb Tests

Planners of the Navy atom bomb test on Bikini Atoll this summer hope to have observers present from every scientific and technical field which might be affected by release of atomic energy, including medical scientists.

Pretrial Conference for Limb Manufacturers

Judge Bower Broadus of Oklahoma City held pretrial conferences last week with attorneys for most of the eighty-one artificial limb manufacturers and supply firms charged with violation of the Sherman Anti-Trust Act. The judge granted two weeks to the government to prepare documents to be introduced as evidence for authentication. Another week was granted to the defendants to examine documents.

Medical Service Prepayment Plan

The District of Columbia Medical Society has launched a prepayment medical care plan providing limited surgical and obstetric services in the hospital in return for monthly fees paid in advance. It was submitted to Washington physician-members for approval. It will be known as Medical Service of the District.

Venereal Disease Bill to Be Considered March 18

The bill introduced by Representative Bolton, Republican of Ohio, to fight prostitution and venereal disease by continuing activities of the Federal Security Agency's social protection division will be considered at hearings of a House Judiciary subcommittee on March 18.

Progress in Drive for Nurses' Memorial

Progress is reported in the drive to erect a nurses' center in Washington as a memorial to nurses who served during the war. Mrs. Norman Kirk, wife of the Surgeon General of the Army, is sponsor of the drive.

Medical Legislation

MEDICAL BILLS IN CONGRESS

Veterans Administration

Congressman Rogers, New York, has introduced H. R. 5685, to provide for the national health and productive power of the people of the United States by clarifying the laws pertaining to hospital treatment, medical care, domiciliary care and related services. The bill provides that any center, hospital, home or clinic, now or later under contract, control and jurisdiction of the Veterans Administration, War Department, Navy Department or Public Health Service shall be available for the admission of any veteran of any war, military occupation or military expedition since 1897, not dishonorably discharged, without regard to the nature or origin of his or her disease or disability. Prior to the construction of adequate facilities to take care of all veterans requiring hospitalization, the bill proposes, any veteran excluded because of lack of beds shall go to the private hospital of his choice, and the Veterans Administration will be authorized to pay the bill. A hospital building program is proposed involving an expenditure of $550,000,000 to construct 57,000 additional hospital beds. The President will be authorized also to establish six Diagnostic, Research and Proving Centers.

S. 1915, introduced by Senator Langer, North Dakota, provides that the United States Veterans Administration hospital in Fargo, N. D., shall be known as the Clarence Theodore Hoverson Memorial Hospital.

A bill introduced by Representative Fellows, Maine, H. R. 5660, proposes that the provisions of all laws administered by the Veterans Administration which extend benefits to any woman who served honorably as a nurse, chief nurse or superintendent of the Nurse Corps under contract with the United States for ninety days or more between April 21, 1898 and Feb. 2, 1901 be made to apply to any man who served honorably in any such capacity under contract with the United States for ninety days or more between such dates.

District of Columbia

Representative Murphy, Pennsylvania, has introduced H. R. 5650, providing that, notwithstanding any limitation relating to the time within which an application for licensure must be filed, the Commission on Licensure to Practice the Healing Art in the District of Columbia is directed to issue a license to practice the healing art to Dr. Peter Florey, Washington, District of Columbia, in accordance with the provisions of the first paragraph of section 24 of the Healing Arts Practice Act of 1928.

Miscellaneous

H. R. 5686, introduced by Representative Forand, Rhode Island, proposes to authorize so much as may be necessary to enable each state to furnish assistance to needy individuals and to render needed welfare services to recipients of public assistance. If a state plan so provides, medical care may be supplied to the needy individuals.

H. R. 5569, introduced by Representative Cole, New York, would direct the Secretary of the Navy to promulgate regulations providing for the reimbursement of persons in the naval service for the cost of emergency or necessary medical services, including hospital services and medicines, from civilian sources when the person receiving the service is in a duty status.

STATE LEGISLATION

California

Bill Enacted.—A. 88-X has become chapter 56 of the Laws of 1946. It provides for the creation of a State Advisory Council on Hospital Facilities and authorizes the Department of Public Health to make a survey of existing public and private hospitals and health centers in the state, to evaluate the sufficiency of such hospitals and health centers to supply the necessary physical facilities for furnishing adequate hospital, clinic and similar services to the people of the state and to make recommendations concerning additional facilities when necessary.

Kentucky

Bills Passed.—H. 87 passed the senate February 21. To amend the workmen's compensation act, it proposes to increase the number of persons on the medical committee of the workmen's compensation board from three to five and further proposes that such committee shall include at least one surgeon and one neurologist. H. 257 passed the Senate March 1. To amend the law relating to divorce, it proposes to authorize the granting of a divorce when one spouse has become permanently and incurably insane and has been confined in an asylum at least five years prior to filing the suit. In such action the court shall find from the testimony of two or more physicians competent in psychiatry that such insanity is permanently incurable.

Bill Enacted.—S. 56 was approved March 1. It amends the law relating to the practice of pharmacy by providing that applicants for a license to practice pharmacy must be citizens of the United States, must have graduated from a school or college of pharmacy recognized and approved by the Kentucky Board of Pharmacy and must submit proper affidavits showing a minimum of one year of experience in a retail pharmacy under the supervision of a registered pharmacist.

Massachusetts

Bill Passed.—H. 74 passed the House March 5. To amend the law relating to bacteriologic laboratories, it proposes to authorize the Department of Public Health to grant certificates of approval for laboratory tests on milk, food, eating utensils, water and sewerage in accordance with such rules and regulations as the department may establish.

Mississippi

Bills Introduced.—H. 699 proposes to authorize the State Board of Examiners to proceed by injunction to prohibit any person from practicing any profession licensed under the supervision of said board when such person is not duly licensed so to practice. H. 712 proposes to provide for the incorporation of medical, surgical and other corporations organized for improving the physical, mental and moral condition of mankind.

Bills Passed.—H. 72 passed the House February 20. It proposes the creation of a four year medical school as a department of the University of Mississippi which shall be operated as a class A medical school in accordance with the "Council of Medical Education" of the American Medical Association. H. 430 passed the House February 26. It proposes the creation of a Mississippi commission on hospital care to set up and administer a statewide plan for the construction, equipping and maintenance of hospitals, nurses' homes, health centers, clinics and related facilities and in conjunction therewith prepare a statewide hospital plan and to conduct all necessary studies and surveys incident to developing such a statewide hospital plan. H. 431 passed the House February 27. It proposes the creation of a state medical education board to receive and pass on applications for loans or scholarships made by students who are residents of the state and who desire to become physicians. The purpose of such loans will be to enable the applicants to obtain a standard four year medical education which will qualify them to become licensed, practicing physicians and surgeons in the state.

Bill Enacted.—H. 388 was approved March 4. It provides an appropriation to the state board of health for conducting a program of eradication and control of syphilis and other venereal diseases.

New Jersey

Bills Introduced.—A. 183 proposes the creation of a board of naturopathic examiners and defines naturopathy to be "that system of the healing arts which means 'nature cure or health by natural means' and is defined as the prevention, diagnosis and treatment of human ailments and diseases by means of any one or more of the psychological, physical or mechanical, chemical or material forces of nature, excluding drugs, surgery or other artificial measures." The proposal would authorize the naturopathic licentiate "to practice naturopathy within this state and to that end shall have the authority to examine patients, diagnose and treat by natural agencies any disease, pain, injury, deficiency, deformity, ailment or physical or mental condition and to prescribe and regulate the patient's dietary, sanitary and hygienic requirements; also use the x-ray and any other instrument for the purpose of diagnosing, analyzing and determining the patient's ailment . . . ; also shall have the right and privilege to sign all certificates, as is granted to practitioners of other branches of the healing arts, as well as in all matters pertaining to public health welfare and to have the right to employ nurses and to employ the aid of assistants." S. 120 proposes the establishment of a diagnostic center to be fully equipped with all modern scientific equipment and provided with a staff of competent specialists in the field of medicine, psychiatry and psychology, to the end that full and complete diagnostic services shall be available to any governmental agency desiring to secure a complete diagnosis of any individual having need for such services.

New York

Bills Introduced.—A. 1795 and S. 1542, to amend the education law, propose a number of amendments to the law relating to the practice of pharmacy. A. 1959 and S. 1651, to amend the education law, propose the granting of state aid to assure provision for diagnosis, treatment and supervision of physically handicapped children, defined as children under 21 years of age who by reason of a physical defect or infirmity, whether congenital or acquired by accident, injury or disease, are or may be expected to be totally or partially incapacitated for education or for remunerative occupation. A. 1973 and S. 1773, to amend the state licensing law, propose that persons lawfully inducted into the military service who were licentiates under the state law at the time of their induction may apply for a renewal of their license within three months of discharge from the service or within three months of discharge from any period of hospitalization in a facility maintained by the United States Veterans Administration. A. 1974 and S. 1772, to amend the state licensing law, propose to postpone from July 1946 to July 1947 the time during which previous licentiates whose license lapsed during military service may have a renewal license without examination. A. 1985 and S. 1709, relating to licensed professions, propose that any person who was eligible at the time of his induction to obtain a license to practice a healing art shall not be required to meet qualifications additional to those existing at the time of his induction. A. 1995, to amend the education law, proposes to authorize the department to issue a license to practice medicine to any person otherwise qualified therefor who shall, within one year from the date of this law, give satisfactory evidence to the department (*a*) of fitness as to age, character, preliminary and medical education and qualifications, (*b*) that he has successfully passed the examinations required by or pursuant to this chapter in all but one of the subjects specified therein, (*c*) that he has served for a period of more than three years in the armed forces of the United States in time of war and that he was a resident of the state prior to his enlistment or induction, and (*d*) that he was prevented from taking a reexamination in the subject in which he failed to attain a passing grade by reason of such enlistment or induction. A. 2000, to amend the workmen's compensation law, proposes that no claim for services in connection with any separate, lay-owned x-ray laboratory, medical bureau or other laboratory shall be valid and enforceable unless such laboratory or bureau has obtained a license from the chairman of the workmen's compensation board. A. 2020 and S. 1695, to amend the education law, propose to redefine a podiatrist as one "who holds himself out as being able to diagnose, treat, operate or prescribe for any disease, pain, injury, deficiency, deformity or physical condition of the human feet, and who shall either offer or undertake by any means or method to diagnose, treat, operate or prescribe for any disease, pain, injury, deficiency, deformity or physical condition of the same within the following limitations: operations on the feet shall be limited to minor surgery; and the use of anesthesia shall be limited to local anesthetics." A. 2076 and S. 1751 propose that every common carrier, railroad, street railroad and omnibus line carrying passengers for hire shall carry a first aid kit for the convenience of the passengers should an emergency arise for such use. A. 2083 proposes to extend the life of the temporary state commission previously appointed to formulate a long-range health program from March 1946 to March 1947. A. 2140 proposes to authorize qualified dentists or qualified dental assistants to use general anesthetics in the care and treatment of dental patients but would require all such persons to have at their disposal at the time of administering any general anesthesia such necessary drugs, medicines and equipment for resuscitation as the board of dental examiners shall prescribe. A. 2157, to amend the workmen's compensation law, proposes that fees for medical services allowable thereunder shall include roentgenology, physical therapy, pathology and anesthesiology. S. 1572 proposes the creation of a state board of examiners in massage and defines massage as "treating the human body for hygienic or remedial purposes by stroking, kneading, tapping or rolling with the hands or with other instrumentalities for the purpose of relieving, alleviating or reducing affected parts thereof but shall not include reduction of a fracture or dislocation of a bone." The practice of massage is declared to be distinct from the practice of medicine, surgery, osteopathy or chiropody. S. 1626, to amend the public health law, proposes the creation of a board of nutrition control to consist of five members, of which at least one shall be a licensed doctor of medicine. S. 1797, to amend the workmen's compensation law, proposes that physician members of the industrial council shall not be eligible for authorization to render medical care under the act and shall not examine, treat, consult or in any other way care for a compensation claimant either at the request of such claimant or of a carrier. S. 1904 proposes the creation of a temporary state commission to make a survey and study of the social, educational and physical problems of individuals afflicted with cerebral palsy with the view and purpose of devising and recommending a program for the aid, care, treatment and rehabilitation of such persons.

Bills Passed.—A. 896 passed the senate March 4. To amend the law relating to the practice of optometry, it proposes that applicants must be citizens of the United States or must have declared an intention of becoming such. A. 898 passed the senate March 4. To amend the law relating to the practice of podiatry, it proposes that applicants must be citizens of the United States or must have declared an intention of becoming such. A. 899 passed the senate March 4. To amend the law relating to the practice of dental hygiene, it proposes that applicants must be citizens of the United States or must have declared an intention of becoming such. S. 577 passed the senate February 26. To amend the workmen's compensation law, it proposes that physician members of the industrial council shall not be eligible for authorization to render medical aid under the workmen's compensation law and shall not examine, treat, consult or in any other way care for a compensation claimant at the request either of the claimant or of a carrier. S. 1189 passed the senate February 25. To amend the law relating to live pathogenic micro-organisms or viruses, it proposes that persons cultivating or possessing live pathogenic micro-organisms of viruses must satisfy the commissioner of health that such organisms or viruses will not become a menace to the public health and shall register with the commissioner of health The registration must be renewed each year. S. 1354 passed the senate March 4. To amend the law relating to nonprofit medical and hospital service corporations, it proposes to authorize the creation of dental expense indemnity service plans. Dental expense indemnity would consist in reimbursement for dental care provided through duly licensed dentists and in furnishing necessary appliances, drugs, medicines and supplies, prosthetic appliances, orthodontic appliances, precious metal and ceramic restorations.

Rhode Island

Bill Introduced.—H. 749 proposes the creation of a Rhode Island Cancer Commission to establish a hospital to be known as the state cancer hospital. Such hospital would be required to conform with all the rules and requirements of the American College of Surgeons for the standardization of cancer hospitals, including the necessary radium and x-ray equipment for the best treatment of patients afflicted with malignant disease.

South Carolina

Bills Introduced.—H. 1143 proposes an appropriation for the establishment and equipping of a hospital to be erected in Charleston as a part of the medical college of South Carolina and for such other facilities for providing medical training at the medical college as may be considered necessary and advisable by the board of trustees. H. 1157 proposes that no person or combination of persons shall practice or attempt to practice as a dental laboratory technician without a certificate or registration either as a registered apprentice or as a registered dental laboratory technician issued pursuant to the provisions of this act by the state board of dental examiners. The practice of a dental laboratory technician is described as "the fabrication of prosthetic dental appliances, such as the using of gold, other metals or combination of metals, plastics, porcelains, artificial teeth or other materials in the manufacture of appliances worn in the oral cavity, replacing teeth and tissue or worn on or around the teeth."

Virginia

Bills Passed.—H. 257 passed the House February 27. It proposes that any person who has tuberculosis in a communicable form who, having been instructed in writing by the local board of health, department of health or health officer or superintendent of any sanatorium of the state to take precautions to protect the members of his household and the public from being infected by tuberculosis communicated by such person, wilfully refuses to follow such instructions shall be guilty of a misdemeanor. H. 289 passed the senate March 1. It proposes to require persons dealing in the handling and processing of food for human consumption to submit each six months a certificate from a physician duly licensed for that purpose by the State Board of Health, certifying that such person has been examined and found free from any contagious or infectious disease. S. J. R. 20 passed the senate March 4. It proposes the creation of a commission to make a thorough and complete study of problems related to hospital and medical care, including the need of hospitals and health centers in the state, adequate plans for the prepayment of hospital and medical care for all classes of citizens, with due emphasis on the special needs of rural people, and other items related to the health and medical care of the citizens of the state. S. 21 passed the senate March 4. It proposes that the state board of health be authorized to initiate and administer a program of hospital treatment and care for indigent persons residing in the state. S. 149 passed the house March 4. It proposes the creation of hospital authorities to engage in hospital construction, maintenance and operation. S. 237 passed the senate March 1. It proposes the creation of an examining board for the certification of clinical psychologists.

Council on Medical Service and Public Relations

Charles H. Coghlan Assists in Organization of Ohio Plan

Charles H. Coghlan, who has been assistant director of Michigan Medical Service, has been named director of the Ohio Medical Indemnity Company in Columbus.

Coghlan has been in Ohio since the middle of August, assisting in the organization of the Ohio medical plan. Announcement has now been made of his appointment as chief executive of the Ohio Medical Indemnity with the title of executive vice president.

With Michigan Medical Service practically from its inception in 1940, Coghlan has been largely responsible for its growth. He is well versed in the operating problems and technics of medical plans and understands the medical profession's point of view.

The home office of Ohio Medical Indemnity will be in Columbus. Blue Cross plans throughout the state will handle the routine operating procedures.

Federal versus Voluntary Health Insurance: A Statement of the New Castle (Del.) County Medical Society

The New Castle County Medical Society feels that a public statement clarifying its attitude on the important subject of costs of adequate medical care is timely and will be helpful to the community. The members of the New Castle County Medical Society are acutely aware of the desirability of easing the burden of expense from unexpected illness in the American family, particularly in the middle and low income groups, and the need for further extending the benefits of preventive medicine for the preservation of the health of the nation. It is known that the quality and availability of medical and hospital care in the United States are better than those of any other country. Such medical advancement has necessarily brought about certain increased costs. In New Castle County and in the state of Delaware, as in the country as a whole, a lowering of costs which is compatible with a continuing improvement in the quality of the medical care should be sought.

This society is strongly in favor of voluntary indemnity health insurance plans. It is opposed to any federal control of medicine which will permit, directly or indirectly, domination of medical service by a governmental bureau. Such control has been proposed from time to time and has been called "socialized medicine." This society is in accord with the principles laid down by the House of Delegates of the American Medical Association and we therefore approve the following:

"The allotment of such funds as the Congress may make available to any state in actual need for the prevention of disease, the promotion of health and the care of the sick on proof of such needs.

"The principle that the care of the public health and the provision of medical service to the sick is primarily a local responsibility.

"The continued development of the private practice of medicine subject to such changes as may be necessary to maintain the quality of medical services and to increase their availability."

It is our opinion that federal compulsory health insurance now under consideration in Congress is contrary to these principles and that passage of such legislation will result in increased total costs of medical care, will disturb the age old confidential relationship between the patient and his doctor, will encourage political and bureaucratic control of medicine and eventually will impair rather than improve the quality of medical care received by the citizens of this nation.

From long experience in furnishing medical service both physicians and hospitals know well the reluctance with which a large portion of our population accept such service, even when it is critically needed and no costs devolve on the recipient. This reluctance to accept medical service can be changed only through a widespread and better understanding of the potential contribution of medicine to the preservation of health. This large group of citizens will not immediately accept medical services whether offered voluntarily or extended to them by federal law. Any system will and should fail of its purpose if forced on them. Only by convincing them of the merits of health insurance, and gaining their voluntary acceptance, can insurance succeed. This procedure is being followed now by the voluntary indemnity plans as vigorously as the population is willing to receive it.

In the opinion of the members of the New Castle County Medical Society the best solution to the problem of spreading the costs of medical care and increasing its availability to all persons in Delaware at the present time and under our democratic form of government is through the furtherance of voluntary health insurance plans. Such a plan was approved by this society and has been in operation since 1943. Already 60,000 persons, one fourth of the people of Delaware, are enrolled. By paying a small premium, the subscriber to the plan makes available a specific sum of money to pay on the cost of each specified operation. The amount may or may not equal the surgeon's fee for a particular operation, and if it does not the additional expense is a matter for individual arrangement between the patient and the physician. This plan has thus far been successful with this group. It should be expanded to give wider coverage against the costs of unexpected and untimely illness.

With further experience and with greater interest of the community in medical costs, the voluntary indemnity plan will succeed in accomplishing the desired ends, which are (*a*) to make medical care in Delaware available to all groups, (*b*) to improve the quality of such care and (*c*) to lower its cost. Similar types of service are in operation the country over. Such a plan retains the doctor-patient relationship, whereby the patient can choose any physician he wishes by his own volition and without bureaucratic control. The plan can be adjusted to meet local needs more readily than any federal compulsory plan. The plan is already in operation, and it seems desirable to give it an earnest, vigorous, patient and fair trial. We recommend that this subject be investigated by all interested citizens.

THE STATUS OF THE ENGLISH DOCTOR

In THE JOURNAL, January 26, page 226, appears a statement credited to Capt. Paul K. Maloney, M. C., A. U. S., entitled "The Status of the English Doctor." As was subsequently pointed out, this article was actually written by Major Clifford L. Graves to Captain Maloney. A letter from Dr. Charles Hill, secretary of the British Medical Association, has now been received in which he emphasizes some inaccuracies and misleading statements which are said to be present in the article. The letter follows:

Dear Sir:—My attention has been drawn to the article in your issue of the 26th January 1946 entitled "The Status of the English Doctor," by Captain Paul K. Maloney.

The article contains so many inaccuracies and misleading statements and gives such a false impression of National Health Insurance in Great Britain that I cannot let it pass without protest. It is quite obvious that Captain Maloney has entirely misunderstood the British scheme: both his facts and his inferences are wrong. In almost every line there is some statement that could be challenged, but if I am not to trespass on your space I must select for comment only a few of the more glaring errors.

Captain Maloney's statements about the financial arrangements of the scheme illustrate how misinformed he is and how many mistakes he can pack into a short paragraph. He says that the individual's contribution is 1/7d. a week, of which the employer pays 10d. and the employee 9d. Actually, the sum of 1/7d. a week is the contribution paid by a woman for both National Health Insurance and contributory pension. The combined contribution for a man is 2/-, but his weekly contribution to National Health Insurance alone is 11d. only. It is not true that an additional 3d. a week has to be paid to secure "a very small sickness benefit." Sickness benefit, that is, a cash benefit, is covered by the man's contribution of 11d. The sickness benefit is not 10/- a week, as Captain Maloney states, but 18/- for a man and 15/- for an unmarried woman. He speaks of shopkeepers and pensioners paying 1/5d. a week, but in fact, employers, self-employed persons and pensioners are not included in the National Health Insurance scheme at all.

Then Captain Maloney makes the astonishing statement that 84 per cent of the funds of the scheme is allocated for administrative charges and 12.5 per cent for the doctors' remuneration and warns his readers that this is what may be expected from a national scheme. The amount absorbed in administrative expenses is actually a little over 17 per cent. Captain Maloney has forgotten to make allowance for the payment of sickness benefit, disablement allowance, maternity grant and other benefits. Moreover, the fund does not collect 82/- a year from each insured person. The total contribution of an insured man, his employer and the state amounts to 55/7d. a year.

Captain Maloney asserts that well over 90 per cent of the population is insured under the scheme. The correct figure is about 45 per cent. The dependents of insured persons are not included in the scheme.

The paragraph on the Approved Societies is completely inaccurate.

Captain Maloney's impression of the status of the insurance practitioner is not true to experience. There is no frequent or regular inspection of doctors' records. It is one of the many duties of the small number of Ministry of Health regional medical officers to call on doctors from time to time and satisfy themselves that proper medical records are being kept. The imposition of a penalty is a rare occurrence. During the last year for which statistics are available only 2 out of 20,000 insurance doctors were fined for failing to keep proper medical records, and the fines in these cases were quite small. Captain Maloney's picture of the doctor as the helpless victim of disgruntled patients is unfair. The doctors themselves generally approve the machinery for dealing with complaints against insurance practitioners, and there is full opportunity of appeal.

Captain Maloney makes much of the alleged limitation of the doctor's authority to prescribe drugs. It is not true that he may not prescribe expensive drugs. He may and does prescribe whatever drugs the patient's condition may require. Avoidance of extravagance is all that is asked, and one cannot, surely, object to that. Captain Maloney is inaccurate in his instances. The injection treatment of hemorrhoids has for long been regarded here as within the general practitioner's range of service. The particular case of alleged excessive prescribing quoted by Captain Maloney was not "investigated by Parliament" and, in fact, half the penalty and costs were remitted after enquiry.

And so I could go on, but I think I have said enough to show that no credence should be given to Captain Maloney's presentation of the British National Health Insurance scheme. We know that the system is by no means perfect and that it has some serious defects, more especially the absence of provision for the dependents of insured persons and the exclusion of consultant and specialist treatment. But on the whole, and so far as it goes, it is a good scheme and works well, and British doctors have a right to expect that when a writer takes it upon himself to describe the scheme to the profession in another country he will make some effort to verify his facts.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education and public health.)

GEORGIA

Ophthalmologic Seminar Honors One Hundredth Anniversary of Abner Calhoun.—Emory University will celebrate, April 4-6, the one hundredth anniversary of the birth of Dr. Abner Wellborn Calhoun, born April 16, 1845, died Aug. 21, 1910, the first professor of ophthalmology of the Atlanta Medical College. Among the speakers in a seminar will be:

Dr. Frank B. Walsh, Baltimore, Myasthenia Gravis.
Dr. Parker Heath, Detroit, Ocular Therapeutics in Glaucoma.
Dr. John H. Dunnington, New York, Surgical Treatment of the Vertical Deviations.
Dr. Walter I. Little, Philadelphia, The Clinical Diagnosis of Retrobulbar Neuritis.
Dr. William L. Benedict, Rochester, Minn., Preparation of the Patient for Cataract Operation.
Dr. Derrick T. Vail Jr., Chicago, The Circulation of the Optic Nerve and Its Influence on Disease.

A feature of the anniversary celebration will be the dedication of the main auditorium of the new Academy of Medicine to the memory of Dr. Calhoun. A portrait will be unveiled and presented to the academy.

ILLINOIS

Eldred Thiehoff Directs Peoria Health Unit.—Dr. Eldred V. Thiehoff, Lansing, recently director of the bureau of local health service, Michigan State Department of Health, has been appointed health commissioner of Peoria, succeeding the late Dr. Sumner N. Miller. Pending the permanent appointment as commissioner, Major George P. Gannon, U. S. Public Health Service, has been acting commissioner. He will remain with the health department to be in charge of the venereal disease program.

Chicago

Personal.—Dr. Walter G. Maddock, associate professor of surgery at the University of Michigan Medical School, Ann Arbor, has accepted a similar position at Northwestern University Medical School.

The Kretschmer Memorial Lecture.—The fifth Edwin R. Kretschmer Memorial Lecture will be delivered on April 26 at the Palmer House by Dr. Charles A. Doan, dean and director of medical research, Ohio State University College of Medicine, Columbus, on "Marrow Hematopoiesis (Synthetic Folic Acid) and Splenic Hematopenia: Experimental and Clinical Studies."

George Whitecotton Goes to California.—Dr. George O. Whitecotton, superintendent of the University of Chicago Clinics for the past seven years, has been appointed medical director of the Alameda County Institutions, Oakland, Calif., to succeed the late Dr. Benjamin W. Black. In addition to his activities as medical director of all county institutions, Dr. Whitecotton will serve as superintendent of the 500 bed Highland-Alameda County Hospital, Oakland, where he spent the years 1932-1936 as intern, senior resident and administrative assistant.

Dr. Huggins to Stay on University of Chicago Staff.—Dr. Charles B. Huggins, professor of surgery (urology) and head of the department of urology, University of Chicago School of Medicine, said on March 7 that he had reconsidered and withdrawn his acceptance of an offer to become director of the Brady urology clinic at Johns Hopkins University School of Medicine, Baltimore (The Journal, January 26, p. 234). Dr. Huggins said that acceptance of the offer would interfere with his research, which, he added, was incomplete and "in a confidential stage."

IOWA

Editorial Board.—An editorial board has been set up for the *Journal of the Iowa State Medical Association* to aid the editor, Everett M. George, Des Moines. The board consists of John W. Dulin, Iowa City; Horace M. Korns, Dubuque, and Ernest E. Shaw, Indianola.

MINNESOTA

Examination for Venereal Disease Control Position.—The Civil Service Commission of the City of Minneapolis announces a civil service examination to fill the position as director, venereal disease control, for the city of Minneapolis. Because the time is limited, persons wishing information concerning the position should write directly to Mrs. Florence R. Dwyer, acting secretary and chief examiner, city of Minneapolis, Civil Service Commission, 109 City Hall, Minneapolis. The beginning salary will be $5,000; applications will close April 30.

New Professor of Psychiatry.—Dr. Donald W. Hastings, former chief psychiatrist of the Eighth Air Force in England and later chief air force psychiatrist in Washington, has been appointed by the University of Minnesota Medical School Board of Regents, Minneapolis, as professor and head of the department of neuropsychiatry in the medical school, effective March 16. Dr. Hastings will fill the vacancy left by the illness and resignation of Dr. John C. McKinley. Since his release from the army in August 1945, Dr. Hastings has served as professor of psychiatry at the Women's Medical College of Pennsylvania, Philadelphia. He graduated at the University of Wisconsin Medical School, Madison, in 1934.

Course for Physical Therapy Technicians.—The section on physical medicine of the Mayo Clinic, Rochester, plans to offer noncredit three months graduate or refresher courses, beginning July 1. The course will be offered without tuition and will be limited to twenty students, who will be taken only from regular courses for physical therapy technicians which have been approved by the Council on Medical Education and Hospitals of the American Medical Association. A second graduate course is planned to start October 1. These refresher courses are intended to supplant the regular emergency course for the training of physical therapy technicians, which will be discontinued July 1, when the present class completes its training (The Journal, Sept. 15, 1945, p. 222).

MISSISSIPPI

Dr. Pankratz Named Acting Dean at Mississippi; Other Changes.—Dr. David S. Pankratz, professor of anatomy, University of Mississippi School of Medicine, University, since 1939, has been made acting dean. He succeeds Dr. Billy S. Guyton, who has been acting dean since the resignation of Dr. James B. Looper in June 1945. Dr. Guyton resigned on February 18 to become dean emeritus and professor of surgery. Dr. Pankratz has been assistant dean and chairman of the department of anatomy since June 1945. Other changes in the faculty include the promotion of Ray J. Nichols, Ph.D., associate professor of anatomy, to professor of microanatomy; the appointment of Dr. Marcus E. Norrison as assistant professor of pathology, bacteriology and clinical laboratory diagnosis; the appointment of George P. Blundell, Ph.D., acting assistant professor of pathology and bacteriology, and the appointment of Dr. William T. Tyson Jr., recently released from the army, as acting associate professor of pathology, filling the vacancy that occurred when Dr. Robert M. Moore resigned in June 1945.

NEBRASKA

Dr. Selby Resigns as State Health Officer.—Dr. Claude A. Selby, state director of health since November 1942, resigned, effective January 31. Dr. Selby had been in private practice in North Platte when he entered the state service. He is a former president of the Nebraska State Medical Association. Dr. Wallace S. Petty, Lincoln, director of the divisions of local health services and communicable disease control, was named director of health. Dr. Petty has been a member of the Nebraska State Board of Health since January 1942. Dr. Roland H. Loder, Lincoln, director of the division of maternal and child health, is on leave at the University of Michigan Medical School, Ann Arbor, where he is completing work for his M.P.H. degree. Dr. Donald M. Alderson, Lincoln, assistant director, will be in charge during Dr. Loder's absence.

NEW JERSEY

Hospitals Cooperate in Plans for Medical Center.—The New Jersey Orthopaedic and Orange Memorial Hospitals, Orange, will be consolidated in a plan to establish a medical center serving the whole northern New Jersey area. The projected medical center will include an $800,000 building for New Jersey Orthopaedic to be built o [illegible] ange Memorial. The present New Jersey [illegible] will then be converted into a hospital for convalescent patients, filling a long felt need for the entire northern New Jersey territory. The new convalescent hospital will operate as a separate agency, and the Memorial and Orthopaedic hospitals will retain separate identities, though they will occupy adjacent buildings and work closely together. A joint committee representing hospitals and other health and welfare agencies plans to undertake a campaign for $1,500,000 to implement the program.

NEW YORK

Stockton Kimball Named Acting Dean at Buffalo.—Dr. Stockton Kimball, Buffalo, on February 28 was appointed acting dean of the University of Buffalo School of Medicine. Dr. Edward W. Koch, dean for sixteen years, died February 9. Dr. Kimball graduated at Buffalo in 1929. He was appointed instructor in medicine and pharmacology in the medical school in 1935, later promoted to associate and in July 1944 made assistant dean.

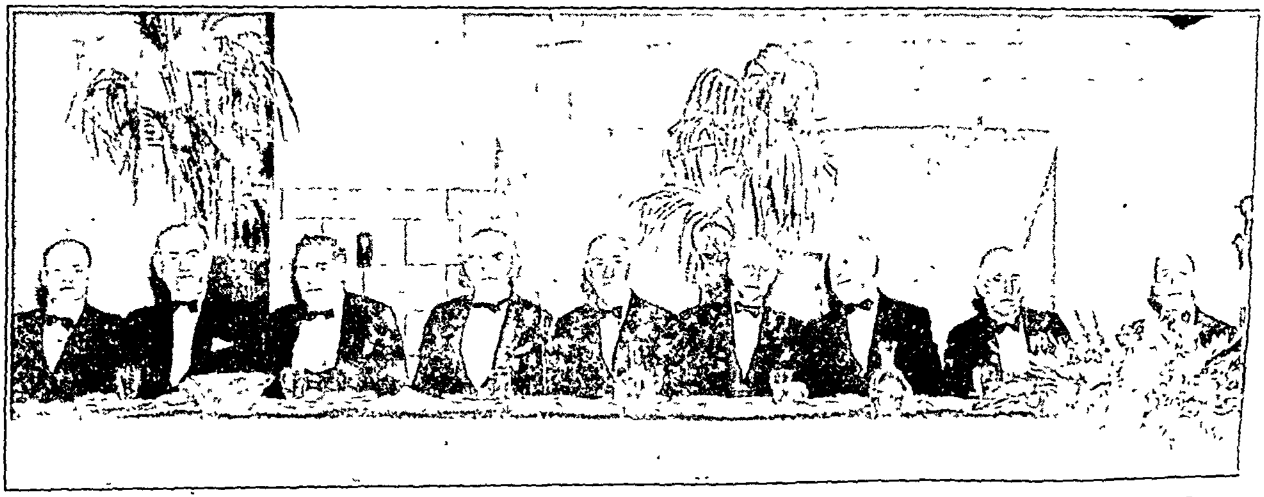
Bill Proposes to Honor Roswell Park.—A bill (S. 341) pending in the current state legislature proposes to change the name of the State Institute for the Study of Malignant Diseases to the Roswell Park Memorial Institute. One of the reasons for the change is that it has been found that many persons are deterred from seeking treatment at the institute because of the word "malignant" in its title, and physicians have been reluctant to send persons there because they did not wish to frighten their patients when they suspected a diagnosis of malignant disease but were uncertain. Another reason is the wish to honor Dr. Roswell Park, who, while professor of surgery at the University of Buffalo School of Medicine, was influential in obtaining an appropriation from the state to establish what was known as the New York State Pathological Laboratory of the University of Buffalo in 1898, becoming its first director. In 1902 the name was changed to the Cancer Institute of the New York State Board of Health, and Dr. Park continued as director. In 1904 he retired as director and became the chairman of the board of trustees, which position he retained, both while the institute was under its latter name and after it became the State Institute for the Study of Malignant Diseases, until his death in 1914.

Millions Asked for Health.—In a special message to the legislature Governor Thomas Dewey recommended March 4 that the state embark on a greatly enlarged health improvement program costing $14,000,000 a year as compared with the present $3,000,000, according to the New York *Times*. One of the main goals set is the elimination of tuberculosis within twenty years under a "master plan." The program is based on the findings of a special interdepartmental committee headed by Dr. Edward S. Godfrey Jr., commissioner of health, which has been studying the subject since last summer. Besides the intensified fight against tuberculosis, the governor called for additional state financial assistance to local health departments and expansion of their services, inauguration of a recruitment and training program for physicians and nurses in the public health field, establishment of an interdepartmental health council and development of new public health programs. The message outlined a four point plan of attack on tuberculosis that included payment by the state of half the cost of hospitalizing victims, abolition of the means test for admission to approved public sanatoriums and hospitals, inauguration of an intensive case-finding method through mass x-ray examinations and participation by the state in research into the prevention and care of tuberculosis. In a discussion of the fifth point of his broader health program, the governor indicated that state assistance would be supplied for health services in parochial and private schools as well as in the public school system. "It makes little sense to provide adequate health services for children of school age through the public school and, on the other hand, to neglect the children who attend schools other than the public schools," he stated. Most of the additional cost of the enlarged program represents new state assistance to municipal and county health and hospital departments. Of the $11,000,000 increase contemplated, about $5,800,000 would go to New York City. Of this $3,000,000 would be for hospitalization of the tuberculous and $2,800,000 for expansion and operation of the health department. The governor took cognizance of the widely divergent views on health insurance expressed by members of a state commission that studied the subject. "Obviously this problem must await further study and disposition by the Congress of bills on this subject pending before it," he stated.

New York City

Harvey Society Lecture.—Dilworth W. Woolley, Ph.D., associate, Rockefeller Institute for Medical Research, will deliver the sixth Harvey Society Lecture of the current series at the New York Academy of Medicine, March 21. Dr. Woolley will speak on "Biological Antagonisms Between Metabolically Important Compounds and Their Analogues."

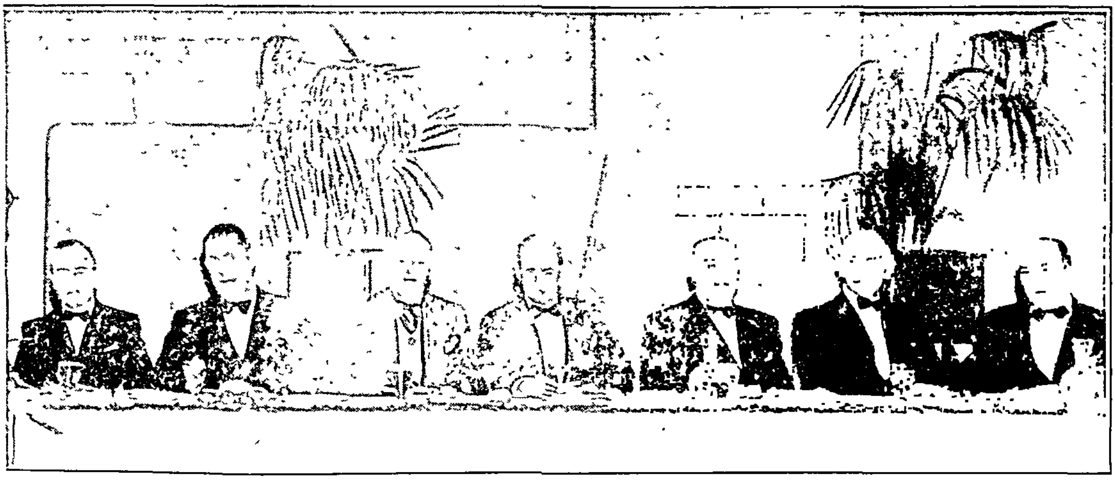
Presidents' Dinner.—The Medical Society of the County of Kings and the Academy of Medicine of Brooklyn held a dinner February 20 to honor four immediate past presidents of the county medical society. The society voted the annual dinner honoring the retiring presidents in 1941 but discontinued the practice during the war. Guests of honor were Drs. William C. Meagher 1942, John J. A. Gainey 1943, Leo S. Schwartz 1944 and Joseph Tenopyr 1945, all of Brooklyn. The physicians were given medals and scrolls. Dr. Thurman B. Givan, president of the Medical Society of the County of Kings, was toastmaster. In addition to the guests of honor, sixteen ex-presidents of the society were present at the dinner. Seated at the speakers' table were Dr. Charles F. McCarty, Brooklyn, secretary; Dr. Ignatius P. A. Byrne, Brooklyn, chairman of the dinner committee; Dr. Henry J. Barrow; Dr. Jean A. Curran, dean and president of the Long Island College of Medicine, Brooklyn; Dr. William B. Rawls, chairman, coordinating council of the five county medical societies; Dr. Abraham Koplowitz, Brooklyn, president-elect, Medical Society of the County of Kings; Dr. Tenopyr; Dr. Gainey; Dr. Morris Fishbein, Chicago, Editor of The Journal, who spoke on "Medicine in the Postwar World"; Dr. Givan; Dr. Edward B. Bernecker, newly appointed commissioner of health; Dr. John J. Masterson, Brooklyn, member of the executive committee, Medical Society of the County of Kings; Dr. Meagher; Dr. Schwartz, Dr. William C. White, president, Medical Society of the County of New York, and Dr. Vincent D. Juster, Jamaica, president, Medical Society of the County of Queens.



Drs. Charles F. McCarty, Ignatius P. A. Byrne, Henry J. Barrow, Jean A. Curran, William R. Rawls, Abraham Koplowitz, Joseph Tenopyr, John J. A. Gainey, Morris Fishbein.

Long Island Plans Expansion.—The Long Island College of Medicine, Brooklyn, has announced that a contract has been signed to purchase all but a small portion of a 6½ acre tract of land facing Kings County Hospital, Brooklyn, for an additional campus for the medical college. It is proposed that the buildings the college now utilizes on Henry Street in downtown Brooklyn be redeveloped as a clinical teaching center in cooperation with the Long Island College Hospital and that new basic science and other teaching facilities and research laboratories be built at the Kings County site. Proposals to extend the industrial medicine activities of the college are being incorporated in the planning for the Henry Street campus. The college expects to continue its "multicenter" plan of clinical teaching, in which ten hospitals and two health agencies in Brooklyn now cooperate, and to extend its affiliations where definite gains in the educational, research or service phases of the program are indicated. It was pointed out that the additional campus was being acquired on the recommendation of the faculty. After lengthy study it was recommended that the college should seek to locate its basic science facilities at the Clarkson Avenue campus while dividing its clinical teaching as at present among various hospitals, both public and private. This would free laboratory space on Henry Street for use in connection with important advances in clinical instruction and for graduate and postgraduate work. Brooklyn State and Kingston Avenue hospitals are adjacent to the Kings County Hospital. The three together contain 6,655 beds, probably the largest aggregate of hospital beds in the eastern United States. The Long Island College division of Kings County Hospital, where the college has had a teaching affiliation for a number of years, includes the branches of medicine, surgery, obstetrics and gynecology and pediatrics and the laboratory sciences in pathology, bacteriology and biochemistry. Its students also study at the Brooklyn State and Kingston Avenue hospitals.

Edward Bernecker Named Commissioner of Health.—Dr. Edward M. Bernecker on March 4 was appointed by Mayor William F. O'Dwyer commissioner of health to succeed Dr. Ernest L. Stebbins, who resigned to become professor of public health administration in the Johns Hopkins School of Hygiene and Public Health, Baltimore (The Journal, Nov. 10, 1945, p. 757). At the same time Mayor O'Dwyer named Dr. William F. Jacobs, medical superintendent of Bellevue Hospital, to succeed Dr. Bernecker as head of the city department of hospitals. In appointing Dr. Bernecker, the mayor is reported to have ignored a recommendation of a special committee (The Journal, March 9, p. 659) he had named to consider a successor to Dr. Stebbins. Dr. Thomas Parran, chairman of the committee and Surgeon General of the U. S. Public Health Service, in a statement to the press said that Dr. Stebbins had resigned "effective immediately" when the mayor failed to name one of the eight physicians recommended March 1. Meanwhile the mayor conferred with a group of physicians representing five medical societies in the city. Their chairman, Dr. William B. Rawls, described the naming of Dr. Bernecker and Dr. Jacobs as "splendid appointments." The physicians recommended by the Parran committee were Dr. Hugh R. Leavell, former health commissioner of Louisville, Ky.; Dr. James E. Perkins of Delmar, N. Y., a deputy commissioner of the New York State Department of Health; Dr. David D. Rutstein, now deputy health commissioner of New York; Dr. Edward S. Rogers, an assistant commissioner of the New York State Department of Health; Dr. Myron E. Wegman, a former deputy in the Maryland Health Department, now attached to the New York City Health Department; Dr. Herbert R. Edwards, acting head officer of the Kips Bay Health Center; Dr. Alexander D. Langmuir, a former deputy health commissioner of Westchester County and now in the army, and Brig. Gen. Stanhope Bayne-Jones, former dean of the Yale University School of Medicine.



Thurman B. Givan, Edward M. Bernecker, John J. Masterson, William C. Meagher, Leo S. Schwartz, William C. White, Vincent D. Juster.

OHIO

Postcollegiate Assembly.—On March 27 the Ohio State University College of Medicine, Columbus, will resume the annual postcollegiate assembly. The following program will be presented by members of the faculty:

Howard L. Bevis, LL.D., The Program for the Medical College in the University Planning.
Dr. Warren E. Wheeler, Pediatric Problems in the Postwar Period.
Dr. Shelby G. Gamble, Physical Medicine, Its Growing Importance in Modern Medical Practice.
Dr. Arthur M Culler, Progress in Ophthalmologic Practice and Research.
Dr. Herman A. Hoster, The Present Status of Cancer Research on the Campus at Ohio State University.
Rollo C. Baker, Ph.D., The Background of Our Medical Center.
John B. Fullen, The Place of the Medical Alumni in University Planning
Dr. Charles A. Doan, The Current Personnel and Physical Expansion of the College of Medicine: Its Teaching and Research Programs.
Dr. William G. Myers, Some Applications of Atomic Energy to Diagnosis and Therapy.
Dr. Allan C. Barnes, The Future of Obstetric and Gynecologic Practice.
Dr. Robert M. Zollinger, Current Problems in General Surgery and Their Solution.

Dr. Hymer L. Friedell, Rochester, N. Y., executive officer, Manhattan Project Medical Research Section, as guest lecturer, will discuss "The Effects of the Atomic Bomb at Hiroshima."

University News.—*Albert Baird Hastings, Ph.D.*, head of the department of biologic chemistry, Harvard Medical School, Boston, will address the commencement at Western Reserve University School of Medicine, Cleveland, March 18 on "Chemical Sectors of Medicine's Frontier." Eighty-two men and one woman will receive their degrees, the entire group including seventy-four in the army-navy training programs and nine civilians.

VIRGINIA

Physicians Plan War Memorial.—The Albemarle County Medical Society, February 8, adopted a resolution expressing the society's approval of setting aside a memorial floor in the proposed new University of Virginia Hospital building to honor local men and women who served in World War II.

Stuart McGuire Honored.—The second edition of Dr. John A. Hardy's "Synopsis of the Diagnosis of the Surgical Diseases of the Abdomen," published in 1945, carries the dedicatorial sentence "To Stuart McGuire of Virginia, who embodies the genius and excellence of a lineage of great surgeons, this book is admiringly dedicated." Dr. McGuire once was president of the Medical College of Virginia, Richmond, and an annual lectureship there now bears his name.

WASHINGTON

Health Department News.—Dr. Leonard A. Dewey, Seattle, has recently returned from military service to his position as head of the venereal disease control section of the Washington Department of Health. Dr. Walvin R. Giedt, Seattle, is head of the epidemiology section.

Personal.—Dr. Edwin S. Bennett, Los Angeles, has been named general superintendent of the King County Hospital system with headquarters at Harborview, effective February 1. Dr. Bennett, before his entry into the army, was medical director of the Los Angeles County Hospital

Physician Becomes Missionary.—Dr. Robert S. Sandilands, Montesano, who graduated at Northwestern University Medical School, Chicago, in 1938, plans to give up his practice in Montesano to enter medical missionary work; he will be stationed in Cameroon, French West Africa.

Golf Course Chosen Site for Medical Building.—Buildings for the new medical and dental school at the University of Washington will be located on the northwest corner of the university golf course. An overpass will connect the building with the main campus of the university. Construction is expected to begin early in the summer of 1946, and the building should be ready for occupancy by the fall of 1947.

WISCONSIN

Journal Dedicated to Mr. Braun.—The *Wisconsin Medical Journal* dedicated its December issue to Mr. Will C. Braun, recently retired business manager of the American Medical Association.

Heart Association Formed.—Papers were recently filed in the office of the secretary of state to incorporate the Wisconsin Heart Association, a new group to sponsor and assist in a state program for the prevention of heart disease. Incorporators are Drs. Ovid O Meyer, Nels A. Hill and Chester M. Kurtz, Madison; Alvin G. Koehler, Oshkosh, and Vincent M. Koch, Janesville.

Dr. Sevringhaus Goes to New Jersey.—Dr. Elmer L. Sevringhaus, professor of medicine, University of Wisconsin Medical School, Madison, has resigned to become director of clinical research for Hoffman LaRoche, Inc., in Nutley, N. J., effective about March 15. Dr. Sevringhaus has been a member of the Wisconsin staff since 1921, the year he graduated at Harvard Medical School, Boston.

Trust Fund Created for Young Physician's Children.—A trust fund has been started by associates of Lieut. Commdr. George W. Fox, Milwaukee, who died in action aboard the aircraft carrier *Franklin* after it was bombed by the Japanese near Kobe on March 19, 1945. Dr. Fox was awarded the Navy Cross posthumously for extraordinary heroism under fire. The trust fund is being set up through monies which are still being accumulated to assure a college education for the physician's three children. Dr. Fox was 38 years of age.

Supervisor of Local Health Services Named.—Dr. Allan A. Filek, Madison, was appointed supervisor of local health services by the state board of health at its January meeting. He will also continue his duties as director of the tuberculosis division until a qualified physician can be obtained to fill his former post. A tenth health district comprising Douglas, Washburn, Burnett, Polk and Barron counties, to be put into effect as soon as personnel can be obtained, was approved by the state board of health at its December meeting. Ten districts were authorized by the legislature, but only nine were set up originally. Five districts remain without medical officers, however, and these vacancies will be filled before the new district is staffed.

GENERAL

New Journal on Plastic and Reconstructive Surgery.—The American Society of Plastic and Reconstructive Surgery announces the publication of an official periodical to be known as *Plastic and Reconstructive Surgery*. The first number will appear in July and the journal will be issued bimonthly. One volume of 500 pages will be issued each year and the subscription price will be $6. Dr. Warren B. Davis, Philadelphia, will be the editor, with a board of twelve associate editors. Subscriptions should be sent to the publishers, the Williams and Wilkins Company, Baltimore 2.

National Committee on Medical Care Formed.—Dr. Leverett D. Bristol, commissioner of health and welfare, Maine Department of Health and Welfare, Augusta, has been appointed chairman of the National Committee on Medical Care of the American Public Welfare Association. The committee, made up of leading welfare authorities in the United States, includes state administrators as well as representatives of private agencies. The committee will consider adequate medical care for persons in need, the development of wise administrative procedures to cover the medical aspects of public assistance and a satisfactory program for the care of the chronically ill.

Snow Medal Awarded.—The William Freeman Snow Medal, given annually for distinguished service to humanity, was presented February 6 to Dr. John H. Stokes, director of the Institute for Control of Syphilis of the University of Pennsylvania, Philadelphia. Presentation took place during the annual meeting of the American Social Hygiene Association, New York. It coincided with a similar award in London to Col. Lawrence W. Harrison of the British Ministry of Health. The presentation in London was made by Sir Wilson Jameson, chief of the British Ministry of Health, and was heard at the local gathering by transoceanic rebroadcast.

Norton Award Goes to Edward Hume.—The Norton Medical Award for 1946 has been given to Dr. Edward H. Hume, New York, for his book Doctors East, Doctors West, an American physician's life in China. Doctors East, Doctors West is Dr. Hume's life story of building a medical center in Changsha, China, where the science of the West and the wisdom of the East met and where Chinese and Americans worked side by side in the pursuit and application of medical knowledge. Dr. Hume was born in India, received his education in the United States and spent twenty-five years in China, where he took part in the founding and development of the Yale-in-China Medical School. At present he is secretary of the Christian Medical Council for Overseas Work in New York. Doctors East, Doctors West will be published on May 3.

Morton Seidenfeld Joins Infantile Paralysis Foundation.—Morton A. Seidenfeld, Ph.D., until recently chief clinical psychologist with the rank of lieutenant colonel with the division of neuropsychiatry, office of the Surgeon General, U. S. Army, on February 25 was appointed director of psychologic services for the National Foundation for Infantile Paralysis. In cooperation with the medical director of the national foundation, Dr. Seidenfeld will inaugurate a research program on the psychologic problems and needs of infantile paralysis patients and will develop a plan for their psychologic treatment. Basil O'Connor, president of the foundation, said that Dr. Seidenfeld's appointment will add an important new sphere of activity to the organization's medical program. Based on modern practice in clinical psychology, the projected work will widen the scope of national foundation planning for the treatment of poliomyelitis patients, especially during convalescence, continuing care, and rehabilitation. When he entered the army in 1940 Dr. Seidenfeld had been director of rehabilitation for the Tuberculosis Institute of Chicago and Cook County.

Physicians Literary Guild Organized.—The American Physicians' Literary Guild was organized in San Francisco January 2 as a brother organization to the American Physicians Art Association. Officers include Drs. James C. Janney, Boston, president; Charles H. Best, Toronto, Ontario, Canada; James T. Flexner, New York, Martin Gumpert, New York, and Henry E. Sigerist, Baltimore, vice presidents; Francis H. Redewill, San Francisco, secretary; Paul P. E. Michael, Oakland, treasurer; Frederic N. Loomis, Oakland, chairman of judges, and Max Thorek, Chicago, general adviser. All physicians in America who write as an avocation are invited to join the guild. The group hopes to stimulate the best physician writers to send in their unpublished works to the literary exhibition during the annual session of the American Medical Association. It will also attempt to stimulate all physicians to complete a nonmedical essay, monograph, short story or poem for competitive consideration. For purposes of classification and awarding, literature is divided into fifteen classes with awards of silver and bronze plaques to be awarded first and second prizes respectively. Watch fobs will be awarded to each physician writer who sends in a literary work of merit. There will also be a president perpetual cup for the best medical essay or monograph, a secretary perpetual cup for the most humorous play, short story or poem and a grand prize given outright by Dr. Thorek for the best piece of literature handed in at the exhibition. The manuscript for competition should be nonmedical so as not to compete with writings presented at medical meetings or those published in medical journals. Other classifications include nonfiction: true story, up to World War II and beyond, essays and monographs; fiction: plays (drama, humorous), short story (serious, humorous), poetry (serious, humorous) and novel (romantic, historical, dramatic, action stories). Additional information may be obtained through Dr. Redewill, secretary, Flood Building, San Francisco 2. All manuscripts must be shipped to the secretary before June 1, express collect. After the exhibition the manuscript will be shipped to the author, express prepaid.

CORRECTION

Overtreatment Dermatitis of the Feet.—In an article with this title by Dr. G. B. Underwood in The Journal of February 2, page 255, appears the statement that the product called iso-par has as active ingredients "tars and derivatives." The manufacturer has called attention to the fact that the active ingredients of iso-par ointment are synthetic fatty acids derived from petroleum distillates. The product has been accepted by the Council on Pharmacy and Chemistry.

Deaths

Chester Arthur Stewart ⊕ New Orleans; University of Minnesota Medical School, Minneapolis, 1919; born in Hannibal, Mo., Nov. 6, 1890; professor and director of the department of pediatrics at the Louisiana State University School of Medicine; served as clinical professor of pediatrics at the University of Minnesota Graduate School of Medicine and at his alma mater, where he had also been an instructor in the department of anatomy, instructor in pathology, a fellow in pediatrics and assistant professor of pediatrics; past president of the Hennepin County (Minn.) Medical Society; member of the American Academy of Pediatrics and the Northwestern Pediatric Society; served as president of the Louisiana State Pediatric Society; in 1937 represented the National Tuberculosis Association and the American Academy of Pediatrics at the fourth International Congress of Pediatricians in Rome; served as director at large of the National Tuberculosis Association; formerly consulting pediatrician to the Lymanhurst Health Center and member of the staffs of the Abbott and Swedish hospitals, all in Minneapolis; on the staff of the Charity Hospital, where he died February 8, aged 55, of coronary occlusion.

Frank Spooner Churchill, Bass River, Mass.; Harvard Medical School, Boston, 1890; born in Milton, Mass., Aug. 26, 1864; member and in 1913-1914 chairman of the Section on Diseases of Children, American Medical Association; member and past president of the American Pediatric Society; served during World War I; at one time served on the staff of the Children's Memorial Hospital in Chicago, where he was on the staffs of Cook County and Presbyterian hospitals, medical inspector of the board of health and director of the milk commission; served as physician for the Juvenile Court, Chicago; at one time associate professor of pediatrics at Rush Medical College and member of the board of directors of the Juvenile Psychopathic Institute and the Infant Welfare Society in Chicago; medical assistant, Judge Baker Guidance Clinic, Boston; editor of the *American Journal of Diseases of Children* from 1911 to 1918; died in the Faulkner Hospital, Boston, February 27, aged 81, of heart disease.

John Verne Bohrer ⊕ New York; Cornell University Medical College, New York, 1914; member of the founders group of the American Board of Surgery; member of the American Surgical Association and the American Association for Thoracic Surgery; for many years instructor in surgery, University and Bellevue Hospital Medical College; served as president of the New York Society for Thoracic Surgery; fellow of the American College of Surgeons; director of surgery at the Knickerbocker Hospital; surgeon in charge of the Willard Parker Hospital; died in the New York Hospital December 6, aged 59, of hypertensive heart disease.

Charles Samuel Kibler ⊕ Tucson, Ariz ; Rush Medical College, Chicago, 1914; fellow of the American College of Physicians; member of the American College of Chest Physicians and American Heart Association; specialist certified by the American Board of Internal Medicine; served during World War I; past president of the Pima County Medical Society; on the staffs of St. Mary's Hospital and Sanatorium and Pima County General Hospital; affiliated with the Tucson Medical Center, serving as president of the first staff; co-exhibitor at the 1939 session of the American Medical Association of a display on potassium in hay fever; died February 25, aged 56, of coronary thrombosis.

Clifton Smith Abbott ⊕ Laconia, N. H.; Dartmouth Medical School, Hanover, 1894; past president of the New Hampshire Medical Society; fellow of the American College of Surgeons; for many years secretary and treasurer of the Belknap County Medical Society; on the staff of the Laconia Hospital; died in the Mary Hitchcock Memorial Hospital, Hanover, December 11, aged 74, of a skull fracture received in a fall.

Alfonza A. Aratus, Cincinnati; Louisville (Ky.) Medical College, 1904; died in the Christ Hospital December 1, aged 75, of cardiac and respiratory failure and prostatic hypertrophy.

Wylie McLean Ayres, Cincinnati; Medical College of Ohio, Cincinnati, 1900; at one time professor of clinical ophthalmology at the University of Cincinnati College of Medicine; fellow of the American College of Surgeons; on the staff of the Good Samaritan Hospital, where he died December 22, aged 71, of arteriosclerotic heart disease and myocardial infarction.

Frank Herbert Bartlett ⊕ Muskegon, Mich.; Tufts College Medical School, Boston, 1919; past president of the Muskegon County Medical Society; fellow of the American College of Physicians; medical director and superintendent of the Muskegon County Sanatorium; on the staffs of the Hackley and Mercy hospitals; formerly affiliated with the Central Maine Sanatorium, Fairfield, Maine and Healthwin Hospital (St. Joseph County Tuberculosis Hospital) South Bend, Ind.; died January 25, aged 51, of a skull fracture received in a fall.

John William Birk ⊕ Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1901; fellow of the American College of Surgeons; veteran of the Spanish-American War; on the staff of the Ravenswood Hospital; served as obstetrician and as president of the staff at the Lakeview Hospital; formerly instructor in obstetrics at his alma mater; died December 8, aged 71, of cerebral hemorrhage and chronic nephritis.

Luther Erskin Boone, Chattanooga, Tenn.; Chattanooga Medical College, 1904; died December 6, aged 66.

Leon Maurice Bowes ⊕ Chicago; Rush Medical College, Chicago, 1903; served during World War I; colonel, medical reserve corps, U. S. Army, not on active duty; member of the staff of the Swedish Covenant Hospital, where he died December 24, aged 67, of organic heart disease, coronary sclerosis and arteriosclerosis.

Edwin H. Bradley, Peoria, Ill.; University of Vermont College of Medicine, Burlington, 1891; member of the American Medical Association; past president of the Peoria City Medical Society; for many years a member and at one time president of the staff of St. Francis Hospital, where he died December 23, aged 84, of cardiovascular renal disease and arteriosclerosis.

Theodore Wallingford Brown, Marissa, Ill.; University of Illinois College of Medicine, Chicago, 1940; member of the American Medical Association; began active duty as a first lieutenant in the medical corps, Army of the United States, on Feb. 3, 1943 and relieved from active duty in November 1944; died December 3, aged 35, of injuries received when he fell down two flights of steps.

Augustus Irving Burdeno, Wyandotte, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1883; formerly health officer of Delray and bank president; died December 3, aged 87, of pneumonia.

Jay M. Burgess ⊕ Detroit; Michigan College of Medicine and Surgery, Detroit, 1900; served as coroner; on the staff of the Providence Hospital, where he died December 8, aged 72, of cerebral hemorrhage.

Grover C. Caddell, Hoffman, N. C.; North Carolina Medical College, Charlotte, 1913; member of the American Medical Association; chairman of the board of county commissioners; died in the Moore County Hospital, Pinehurst, December 19, aged 58, of heart disease.

Clyde Clement Carroll, White Mills, Ky.; Hospital College of Medicine, Louisville, 1904; member of the American Medical Association; died December 4, aged 66, of cerebral hemorrhage.

Frank H. Caughell, Hermann, Mo.; University Medical College of Kansas City, 1883; local surgeon for the Missouri Pacific Railroad; postmaster; died November 22, aged 83, of diabetes mellitus.

Henry Dickinson Causey ⊕ Fairmont, W. Va.; University of Maryland School of Medicine, Baltimore, 1911; served during World War I; formerly on the staff of the Veterans Administration Facility in Portland, Ore.; medical consultant for the Consolidated Coal Company; died December 12, aged 64, of heart disease.

Charles Cornelius Clark ⊕ Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1905; fellow of the American College of Surgeons; served during World War I; on the staff of the Jackson Park Hospital, where he died December 28, aged 66, of cerebral thrombosis.

Ralph Deming ⊕ Toledo, Ohio; Hahnemann Medical College and Hospital of Philadelphia, 1902; member of the Radiological Society of North America, Inc., and the Toledo Academy of Medicine; served during World War I; on the staffs of the Robinwood Hospital, Maumee Valley Hospital and the Mercy Hospital, where he died December 4, aged 67, of heart disease.

Jerome De Motte, Odon, Ind.; Medical College of Ohio, Cincinnati, 1896; member of the American Medical Association; died in Evansville November 5, aged 76.

Arthur Norton Donaldson ⊕ Santa Ana, Calif.; College of Medical Evangelists, Los Angeles, 1915; clinical professor of medicine at his alma mater, where he had been professor of physiology; specialist certified by the American Board of Internal Medicine; formerly medical director of the Loma Linda Sanitarium and Hospital in Loma Linda and the Harriman Jones Clinic and Hospital in Long Beach; died in Loma Linda December 16, aged 57, of coronary thrombosis.

Breckenridge Johnson Duckett, Muskogee, Okla.; Medical Department of Grant University, Chattanooga, Tenn., 1900; died in a local hospital November 17, aged 78, of injuries received when he was struck by an automobile.

James W. Fortune, West Lafayette, Ohio; Starling Medical College, Columbus, 1891; died November 10, aged 84, of cerebral hemorrhage.

Robert Franklin Goodman, Boyds Creek, Tenn.; Tennessee Medical College, Knoxville, 1895; died in the General Hospital, Knoxville, November 12, aged 77, of injuries received when he fell under the wheels of a mule-drawn wagon.

William L. Gordon, Washburn, N. D.; University of Louisville (Ky.) Medical Department, 1894; for many years county health officer; died in Bismarck December 9, aged 72, of uremia and terminal pneumonia.

Isaac Lott Gotthelf ⊕ Saguache, Colo.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1904; served as president of the San Luis Valley Medical Society; died in the Denver and Rio Grande Western Railroad Hospital, Salida, December 4, aged 65, of myocarditis.

William Slater Greenleaf ⊕ Atlantic, Iowa; State University of Iowa College of Medicine, Iowa City, 1895; member of the Radiological Society of North America, Inc.; on the staff of the Atlantic Hospital; died December 9, aged 73, of heart disease.

Walter Kingsley Grigg ⊕ Albany, N. Y.; Albany Medical College, 1927; assistant in medicine at his alma mater; on the staffs of the Albany Hospital and the Child's Hospital; attending physician, Albany Guardian Society; died December 8, aged 53, of coronary thrombosis and coronary sclerosis.

Ernest A. Hancock, Ranger, Texas; Bennett College of Eclectic Medicine and Surgery, Chicago, 1889; died December 5, aged 78, of heart disease.

Harmon Howard Hays, Cleves, Ohio; Medical College of Ohio, Cincinnati, 1879; died December 5, aged 89, of arteriosclerosis.

Charles Francis Hester, Newton, Miss.; Mississippi Medical College, Meridian, 1907; died in Rush's Infirmary, Meridian, December 11, aged 65, of lobar pneumonia.

John Morley Hoag ⊕ Baltimore; College of Physicians and Surgeons, Baltimore, 1902; died January 10, aged 70, of coronary thrombosis.

Charles Waln Huffman, Lebanon, Tenn.; Eclectic Medical Institute, Cincinnati, 1894; member of the American Medical Association; died November 7, aged 75, of amebiasis.

Clarence Ludlam Hyde ⊕ Akron, Ohio; University of Michigan Homeopathic Medical School, Ann Arbor, 1906; fellow of the American College of Physicians; medical superintendent of the Edwin Shaw Sanatorium; on the staff of the City Hospital; at one time superintendent of the J. N. Adam Memorial Hospital in Perrysburg, N. Y.; died December 1, aged 67, of coronary thrombosis.

Addison Cornelius McCain, Greeley, Colo.; University of Colorado School of Medicine, Denver, 1904; member of the American Medical Association; on the staff of the Weld County Public Hospital, where he died November 27, aged 69, of carcinoma of the stomach.

John Johnston Miller, San Jose, Calif.; University of Michigan Homeopathic Medical School, Ann Arbor, 1880; served two terms as health officer of Santa Clara County; member of the board of health; died February 8, aged 86, of heart disease.

Lawrence Joseph Rigney ⊕ Wilmington, Del.; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1920; fellow of the American College of Physicians; instructor in medicine at the University of Pennsylvania School of Medicine in Philadelphia; affiliated with the Delaware Hospital and St. Francis Hospital, where he died November 28, aged 55, of rupture of esophageal varix and cirrhosis of the liver.

William Zinke, Collbran, Colo.; Bennett College of Eclectic Medicine and Surgery, Chicago, 1890; member of the American Medical Association; died November 25, aged 79, of heart disease.

DIED WHILE IN MILITARY SERVICE

William Thomas Edmundson, Greeley, Colo.; University of Colorado School of Medicine, Denver, 1944; commissioned a lieutenant (jg) in the medical corps of the U. S. Naval Reserve on Oct. 9, 1944; died in the U. S. Naval Hospital, San Diego, Feb. 4, 1945, aged 23, of atypical primary pneumonia.

Charles Manly Griffith, New York; University of Virginia Department of Medicine, Charlottesville, 1917; born in Lexington, N. C., June 10, 1893; clinical professor of otolaryngology at the New York Post-Graduate Medical School and Hospital, Columbia University; member of the American Medical Association and the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; specialist certified by the American Board of Otolaryngology; consulting otolaryngologist at St. Agnes Hospital in White Plains and on the staff of the Manhattan Eye, Ear and Throat Hospital; commander, medical corps, U. S. Naval Reserve; participated in the South Pacific campaign and had received the Purple Heart and the Navy Cross; died Oct. 9, 1945, aged 52.

Max Leonard Holland ⊕ Roanoke, Va.; Medical College of Virginia, Richmond, 1935; interned at the Baroness Erlanger Hospital in Chattanooga, Tenn., and the Toledo Hospital in Toledo, Ohio; served a residency at the Gill Memorial Eye, Ear and Throat Hospital; began active duty as a captain in the medical corps, Army of the United States, on July 29, 1942; died in Fort Benning, Ga., Nov. 9, 1945, aged 37, of bronchopneumonia.

Harry H. Jackson, Detroit; Detroit College of Medicine and Surgery, 1917; served during World War I; began active duty as a commander in the medical corps of the U. S. Naval Reserve on Aug. 17, 1940; promoted to captain; died in the U. S. Naval Hospital, Jacksonville, Fla., Dec. 17, 1944, aged 51, of ruptured abdominal aneurysm of the aorta.

Raymond Luft, Norwood, R. I.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1934; born in Jersey City, N. J., Nov. 16, 1904; interned at the Royal Victoria Hospital in Montreal, Que., Canada; assistant resident physician at the Massachusetts General Hospital in Boston; past president of the Kent County Medical Society and the Rhode Island Public Health Officers Association; member of the American Medical Association; superintendent of health in the city of Warwick; served on the staff of the Rhode Island Hospital in Providence; began active duty as a lieutenant in the medical corps, U. S. Naval Reserve, on February 28, 1944; assigned to the auxiliary personnel attack ship U. S. S. Henrico and participated in the invasion of Normandy; sent to North Africa later to prepare for the invasion of southern France; became ill and was transferred to a hospital in Naples and shortly afterward came back to the United States; after hospital treatment here he was assigned as medical officer for training units at Harvard and Tufts College, a position he held until he was hospitalized ten days prior to his death; held the European-African-Middle Eastern Area Campaign Medal; died in the Naval Hospital, Newport, June 23, 1945, aged 40, of coronary thrombosis.

Robert Bliss Miller, Argos, Ind.; Indiana University School of Medicine, Indianapolis, 1934; member of the American Medical Association; interned at St. Joseph Hospital in South Bend; began active duty as a captain in the medical corps, Army of the United States, on Dec. 15, 1940; died in the Percy Jones General Hospital, Fort Custer, Mich., April 30, 1945, aged 35, of carcinoma.

Jesse Frederick Steiner Jr., Seattle; Stanford University School of Medicine, San Francisco, 1941; born in Chicago, Oct. 4, 1914; interned at the San Francisco Hospital in San Francisco; served with the Royal Medical Corps of the British army from Sept. 6, 1941 to May 24, 1943, as a first lieutenant and later as captain; transferred to the medical corps, Army of the United States, on May 25, 1943, serving as first lieutenant and later as captain; served with the 16th Field Hospital, which was with General Patton's Third Army during its drive through France and Germany, and earned five battle stars for his European Theater ribbon and the Bronze Star Medal; relieved from active duty Oct. 13, 1945; assistant resident physician at Stanford University Hospital in San Francisco, where he died October 11, aged 31.

The Services to Medicine of the Aslib Microfilm Service

The cutting off in the early days of the war of the scientific periodicals of Germany and of occupied countries presented a serious problem in obtaining information vital to research To meet this difficulty the Association of Special Libraries and Information Bureaus (Aslib) was organized in April 1942 through the cooperation of the Royal Society, the Rockefeller Foundation and British Industry This organization supplied a microfilm service of scientific periodicals published in Germany and occupied countries for use by the British and American governments and by British and American scientific institutions and research centers The library of master negatives accumulated for the purpose contains some 14 000 separate issues of 500 titles The Aslib Microfilm Service supplied China when that country was cut off from ordinary surface transport This service grew so that during the last year 170 periodicals were regularly microfilmed and six positive copies of each were flown to China One hundred microfilm projects set up in a dozen reading centers enabled the Chinese to keep in touch with developments in the outside world

The end of the war reduced the demand for the Aslib Microfilm Service, but there was a need for documentary reproduction A plan for the rehabilitation of the medical libraries in Europe, destroyed or despoiled by the Germans was presented by the Royal Society of Medicine Aslib agreed to the transfer of the Microfilm Service and became an integral part of the Central Medical Bureau of the Royal Society of Medicine Requests for copies from existing master negatives and for copies of individual references may be addressed to Aslib, 52 Bloomsbury Street, London, W C 1

A Residential Rehabilitation Center

A residential rehabilitation center for those injured in the war or in industry has been set up at Egham near the Eton school Employers, trade unions and orthopedic surgeons are convinced that severe disablement and convalescence must be followed by a gradual approach to ordinary employment On a 55 acre estate dormitories, workshops, class rooms and a gymnasium surround a spacious mansion located in well wooded grounds Here 230 men, whom the center can accommodate during courses lasting six to eight weeks, are gradually acclimatized to working conditions by gaining confidence in the manipulation of artificial limbs or overcoming other physical and mental handicaps

Of 1,000 men who have passed through this center, about 500 have returned to former jobs or other suitable occupations, many of the others have entered governmental or other establishment for further training While in residence the men receive free board and lodging and allowances irrespective of their pensions

Congenital Defects Following Rubella in Pregnancy

Only a few years ago an Australian ophthalmologist, N M Gregg (*Tr Ophth Soc Australia* **3**:35, 1941) first drew attention to cataract and other congenital deformities following rubella during pregnancy He reported 78 cases of congenital cataract in babies born between December 1939 and January 1941 in which the mothers, with few exceptions, had suffered in the early months of pregnancy from an exanthem diagnosed as rubella In at least 44 of the infants there was also a congenital lesion of the heart The cataract was of a peculiar type which differs from other congenital types Gregg's observations have been confirmed by other Australian observers In America A B Reese (*Am J Ophth* **27**:483 [May] 1944) reported 3 cases In Britain R E Hope Simpson (*Lancet* **1**:483 [April 8] 1944) reported 3 cases A case has recently been reported to the Section of Obstetrics of the Royal Society of Medicine by Ivor Hughes

Mr Ivor Hughes pointed out that the pathology of such cases is obscure. It has been suggested that the filtrable virus of rubella passes through the barrier of the chorionic villi at a time when lens and septum formation are occurring (sixth to eighth weeks of pregnancy), resulting in ocular and vascular lesions Therefore the percentage of congenital lesions is higher if rubella is contracted during the first three months of pregnancy It has been suggested that it would be justifiable to terminate pregnancy when the occurrence of rubella is proved Mr Hughes does not agree as the percentage of cases of rubella in which fetal defects follow is not known, since only positive cases have been recorded It seems curious that these congenital lesions should be traced to the mildest of the exanthems while none have been observed to follow the more common and more severe infections of measles and scarlet fever Have sequels of these later diseases been overlooked? The congenital lesions of syphilis are analogous to those due to rubella This relationship might long have remained unobserved but for the genius of Hutchinson

Society of Experimental Biology

The Societa Italiana di biologia sperimentale, which did not function during the war, was recently reorganized Dr Gaetano Quagliarello, professor of biologic chemistry at Naples University, was appointed president Branches of the society in Naples, Florence, Rome, Milan and Turin were also reorganized Dr Nello Beccari, professor of comparative anatomy at the Florence University is the president of the branch in Florence The attendance at meetings has been both distinguished and large, indicating the zeal with which the medical profession is trying to make up for the lack of progress during the war In the meetings of the society recently held a number of papers were read Tarantino discussed relations between histidine metabolism and the development of bacteria Pasquinelli reported results of experiments on histidine metabolism in the remaining hyperplastic testis of a guinea pig after removal of one testis The acuteness of histidine oxidation is proportional to the percentage of cells which undergo karyokinesis in the testis The speaker believes that histidine is used by the cells during the process of hyperplasia Donatelli discussed the influence of sex and age on acute mercury poisoning, which he observed in 60 cases The death rate was 83 8 per cent for men and 37 9 per cent for women It was higher in children, adolescents and old persons than in young and mature adults The data were confirmed by experiments on guinea pigs and rats in which the male animals were more resistant than female animals to mercury poisoning That the greater resistance of males is due to testicular hormones was proved by the fact that the resistance to mercury poisoning in males after castration is as low as that of females The administration of synthetic testicular hormones to females increases the resistance of the latter to a level equal to that of normal males Tarantino found by in vitro experiments (Warburg) that the filtrates of cultures of a strain of penicillin which had strong bacteriostatic power prevented consumption of oxygen by Staphylococcus pyogenes aureus The process of dehydrogenation and the glycolytic metabolism of the same species of bacteria was not altered Agonistic effects between substances of the penicillin and sulfonamide (aminobenzaldehyde) groups do not seem to exist

Care of Orphans of Physicians

The care of orphans of Italian physicians who were killed in the war has been in charge of a national committee of which Dr. Siro Fada, the general director of national public health, was president. The committee cared for the orphans until September 1945, although its functions should have ceased in December 1942, according to the original plan. Dr. Fada recently reported to the Ministry of War on the work of the committee. The amount of money collected for this purpose is insufficient. The members of the committee agreed to turn over the remaining funds to the central Opera Nazionale for the care of these orphans. All Italian physicians contribute a monthly sum.

Rio de Janeiro, Feb. 9, 1946.

Diphtheria Investigations

The campaign against diphtheria is gaining impetus in the large cities of Brazil, mainly through the use of active immunization. Drs. Maria C. de Andrade and Jandyra P. do Amaral of the Division of Bacteriology of the Butantan Institute of São Paulo have recently completed an investigation to ascertain the rate of diphtheria carriers among the school children of the city of São Paulo and to determine if the increase in the number of children immunized in recent years is correlated with a reduction in the rate of carriers in this population group. In the public schools 108,952 children have been immunized with three doses of fluid diphtheria toxoid, and 9,891 more have had incomplete immunization. The authors examined 3,071 children from different sections of the city, culturing material from the throat and nose. All cultures considered negative were tested for the fermentation of carbohydrates, for hemolytic power, for virulence and for toxigenic power.

Fifty-eight among the 3,071 children presented positive cultures for the diphtheria bacillus, or 1.88 per cent, a figure that can be contrasted to that of 3.7 per cent obtained by Castro Simões in 1921 in the examination of 1,054 public school children of the same city. The long interval between the two investigations excludes a definite conclusion in favor of a reduction of the rate of carriers, as several epidemiologic factors may have acted to influence the results. The difference between the rate of carriers among the vaccinated children (15 out of 1,072, or 1.40 per cent), and the nonvaccinated (43 out of 1,870, or 2.30 per cent) is not statistically significant, as the authors have pointed out. Nor is there a significant difference between the rate for white (47 carriers in 2,531 children, or 2.85 per cent) and for colored children (11 carriers in 540 children, or 2.04 per cent). It is important to point out that, of these 58 positive cultures, only 1 was of a virulent type and only 9 were toxigenic. If the rate is calculated on the basis of 1 virulent sample, the rate would be reduced to 0.32 per cent.

Hypertension and Pregnancy

Dr. S. Oliveira de Barros and Dr. Justino O. Castro, obstetricians of the Vila Mariana District Health Center, city of São Paulo, have reported several interesting features of 217 cases of hypertension observed among 1,754 pregnancies at the center. The authors decided to use the value 125 mm. as an average systolic pressure based on Brazilian experience; this figure is a little higher than the American value of 120 mm., as suggested by De Lee. They used the value 155 mm. to establish the lower limit of what they call "marked" hypertension, in contrast to "slight" hypertension for the cases with values below 155 mm. They also classify the cases into "acute" and "chronic," using for this distinction the arbitrary limit of the fifth month of pregnancy, based on the assumption that, in the majority of the cases, the hypertension observed in the first months denotes renovascular sclerosis preexistent to the pregnancy, while the pressure change developed from the fifth month on is primarily connected with the pregnancy itself. In the 217 cases the hypertension has been classified as "slight" in 164 (75.6 per cent) and "marked" in 53 (24.4 per cent). In 165 of the cases 68, or 41.2 per cent, have been considered acute and 97, or 58.8 per cent, chronic. In 15 of the cases in which the authors were able to observe one or more subsequent pregnancies, all of them showed the tendency to present higher values for the blood pressure during the later months of gestation.

Cesarean Section and Fertility

Dr. C. Correa la Costa, director of the Arthur Bernardes Maternity Hospital, studied 188 cases of cesarean section performed in previous years in several hospitals of Rio de Janeiro. At the time of the operation 7 patients were between 15 and 19 years of age, 127 between 20 and 29, 50 between 30 and 39 and 4 40 or more. The frequency distribution of the number of pregnancies the women had had before the cesarean section was none in 141 cases, one pregnancy in 25 cases, two or three pregnancies in 12 cases, four or five pregnancies in 5 cases and six or more pregnancies in 5 cases. After the cesarean section 108 women of the 188 have again conceived one or more times (57.4 per cent of fertile cases) and 80, or 42.6 per cent, have been sterile. Of the 80 women included in the sterile group, 2 died as a consequence of the cesarean section, 2 were subjected to ligation of the oviducts and 1 was subjected to hysterectomy. It was ascertained that, among 80 sterile women after the operation, 38 used contraception. There were 28 cases of postoperational sterility, or 32.5 per cent, studied two to three years after cesarean section. Of 46 cases after a four to five year interval there were 10 cases of postoperational sterility, or 21.7 per cent. Of 56 cases in which the interval was six or more years there were 3 cases of postoperational sterility, or 5.3 per cent. Dr. Costa points out that the sterility rate diminished as the time interval between the operation and the investigation increased. These figures indicate that cesarean section does not lead to loss of fertility.

Personal

Admiral Oswaldo Palhares of the Brazilian Navy Medical Corps has been appointed surgeon general of the corps, succeeding Admiral Fabio de Vasconcellos, who had occupied the post since October 1943. Admiral Palhares has announced his general policy, which includes the creation of the Navy Medical School.

Dr. James A. de Tomasi, professor at Cornell University, is spending some time in Brazil, making studies of biology in the cities of Ouro Preto, Diamantina, Sabará and Congonhas, all in the state of Minas Gerais.

Marriages

Randolph Armistead Cate, Nashville, Tenn., to Miss Marcella Shinnick of Thompson, N. D., at Fort Lewis, Wash., December 31.

John W. Jansonius, Eldora, Iowa, to Miss Fern Maria Rippee of Hartville, Mo., in Bloomington, Ind., December 23.

Richard George Whiting, Medford, Mass., to Miss Christine Rosemary Wilson of London, England, January 14.

William Duer James Jr., Hamlet, N. C., to Miss Sara Brooks Nair of Clifton Forge, Va., January 29.

James Franklin Land, Youngstown, Ohio to Miss Elizabeth Jane Morrison of Kokomo, Ind., December 29.

Herman Pepper to Dr. Genevieve Ellen Gaard, both of Redwood City, Calif., in Seattle, February 8.

Hugh Dortch Jr. to Miss Mae Joyce Whitfield, both of Durham, N. C., February 2.

Richard R. Bobb, Lykens, Pa., to Miss Elma Faye Knorr at Paxtang, January 18.

Correspondence

SALICYLATE-INDUCED HYPOPROTHROMBINEMIA

To the Editor:—The communication from Lieutenant Colonel Higley in The Journal, Dec. 15, 1945, page 1123, concerning the clinical significance of salicylate-induced hypoprothrombinemia, prompts the following comments.

According to Shapiro (Studies on Prothrombin: VI. The Effect of Synthetic Vitamin K on the Prothrombinopenia Induced by Salicylate in Man, The Journal, June 24, 1944, p. 546) "there are no fixed levels of prothrombinopenia at which bleeding is known to be established." Therefore a prolongation of the prothrombin time from 14 to 20 seconds may well constitute a "dangerous disturbance." Various statements from authoritative sources reflect the concern—which Dr. Higley apparently does not share—in professional circles here and abroad with respect to the possibility of salicylate-induced hypoprothrombinemia being a factor in the causation of hemorrhages. For instance, The Journal saw fit to caution in an editorial (Is Aspirin a Dangerous Drug? March 18, 1944, p. 777) that patients "who are to receive large doses for a long time may appropriately be given vitamin K." Similarly, Fashena and Walker (Salicylate Intoxication: Studies on the Effects of Sodium Salicylate on Prothrombin Time and Alkali Reserve, *Am. J. Dis. Child.* **68**:369 [Dec.] 1944) state, with reference to salicylate therapy in children, that "the concomitant administration of vitamin K is indicated." Another editorial in The Journal (Hazards in the Salicylate Treatment of Rheumatic Fever, Feb. 24, 1945, p. 460) contains the statement:

> Rheumatic fever often is accompanied by a widespread vascular damage, thus increasing the hazards of hemorrhagic complications after salicylate administration. When adequate amounts of vitamin K are given with salicylates, much of the danger of these complications may be prevented. Possible hazards in the administration of salicylates should be remembered, so that unnecessary dangers may be avoided.

And in an editorial of the *British Medical Journal* (Toxicity of Salicylates, July 7, 1945, p. 19) we read "The danger from diminished prothrombin can fortunately be removed by the simple expedient of giving the patient vitamin K or a related substance such as menaphthone (B. P.). . . . No doubt the regular use of menaphthone together with salicylates will gradually become established." Similarly the *Lancet* contains the following statement under Annotations (Salicylates and Hemorrhage, Oct. 2, 1943, p. 419): "There seem to be good grounds for giving vitamin K . . . prophylactically to patients having large and continued doses of salicylates."

Indeed, precautionary measures in this direction are warranted since even fatalities have been reported in which salicylates appeared to be the lethal factor. For instance, Ashworth and McKemie (Hemorrhagic Complications, with Death Probably from Salicylate Therapy, The Journal, Nov. 25, 1944, p. 806) have observed two deaths from extensive hemorrhages, particularly involving the brain, following administration of large doses of salicylate. Autopsy findings suggested as probable cause of the fatal outcome "a combination of capillary damage and hypoprothrombinemia produced by the salicylates."

Troll and Menten (Salicylate Poisoning, Report of 4 Cases, *Am. J. Dis. Child.* **69**:37 [Jan.] 1945) have reported three fatalities out of 4 cases of salicylate poisoning. In their cases, too, autopsy revealed widespread capillary hemorrhages.

While the number of those who take salicylates with impunity may be legion, reports as the aforementioned indicate that the prevention of prothrombinopenia by concomitant vitamin K administration may make the difference between life and death in some cases.

Lieutenant Colonel Higley takes exception to an article by Capt. Rudolf Singer (Acetylsalicylic Acid—A Probable Cause for Secondary Post-Tonsillectomy Hemorrhage: A Preliminary Report, *Arch. Otolaryng.* **42**:19 [July] 1945), who on the basis of clinical observation concluded that the prothrombinopenic effect of salicylates "seems to be a plausible explanation for the occurrence of secondary post-tonsillectomy hemorrhages."

My report Late Secondary Tonsillar Hemorrhage: I. Studies of Prothrombin and Vitamin K (*Arch. Otolaryng.* **42**:14 [July] 1945) seemingly escaped the attention of Lieutenant Colonel Higley. In studies conducted at the Pharyngology Research Laboratory, Department of Otolaryngology, Columbia University College of Physicians and Surgeons and Presbyterian Hospital, we were able to prove that a hypoprothrombinemic state induced by salicylate medication is one of the most important factors in the etiology of secondary tonsillar hemorrhage; furthermore, that by using a vitamin K preparation such as Synkayvite in conjunction with acetylsalicylic acid, the prothrombin-lowering effect of the latter was rendered ineffectual and that this was followed by a decidedly decreased bleeding incidence.

It is noteworthy that these two communications, Singer's and mine, appeared in the same issue of the *Archives of Otolaryngology* and that they were abstracted in the same issue of The Journal.

The study of drug-induced prothrombinopenias has been taken up only recently and, to be sure, the evaluation of the clinical significance of some of the observations awaits further investigation.

Nevertheless, as a worker in the field, I have had adequate experience to be convinced that salicylate-induced hypoprothrombinemia is of definite clinical importance. I should like to state my opinion that the prevention of such prothrombinopenia by administration of vitamin K in conjunction with acetylsalicylic acid, as suggested by The Journal, the *Lancet* and the *British Medical Journal*, is indeed warranted.

Harry Neivert, M.D., New York.

TREATMENT OF BLACK WIDOW SPIDER BITE

To the Editor:—In relation to the observations made by Drs. Bell and Boone in The Journal, Dec. 8, 1945 related to black widow spider bites, I wish to state the following:

Here, among us, there has been, for many years, a way of combating the intoxication caused by the sting or bite of the scorpion, spiders such as the black widow, and certain other intoxications caused by the bite or sting of other animals or insects not always readily discovered, by means of injections of a 10 per cent aqueous solution of magnesium or sodium thiosulfate as described in the National Formulary VII.

The only caution required in a treatment of this nature is the application of successive doses until symptoms of intoxication disappear permanently. Apparently there is a neutralization of the toxins in a direct manner by means of the thiosulfate ions. As we are never able to know in such cases the toxic dose injected by the animal or the degree of toxicity of the substance injected, care must be exercised to repeat successive doses until permanent disappearance of toxic symptoms.

M. A. Pulido, M.D., Guadalajara, Mexico.

To the Editor:—The article on page 1016 of The Journal, Dec. 8, 1945, exemplifies a lack of knowledge concerning the dynamics of action of Latrodectus mactans toxin. The toxic action mimics overdosages from strychnine, physostigmine and neostigmine. The treatment of choice, as far as drugs are concerned, is to use curare or drugs with a curare-like action. The extreme pain and myotonia may be relieved in five minutes, not six and one-half hours, by the intramuscular or intravenous use of a sterile 25 per cent solution of magnesium sulfate.

P. L. Davis, M.D., East Orange, N. J.

Bureau of Investigation

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the Federal Security Agency

[Editorial Note.—These Notices of Judgment are issued under the Food, Drug and Cosmetic Act, and in cases in which they refer to drugs and devices they are designated D.D.N.J. and foods, F.N.J. The abstracts that follow are given in the briefest possible form: (1) the name of the product; (2) the name of the manufacturer, shipper or consigner; (3) the date of shipment; (4) the composition; (5) the reason for the charge of misbranding, and (6) the date of issuance of the Notice of Judgment.]

Cruez Herb Douche, Cruez No. 9 Herb Tea and Cruez No. 10 Herb Tea.—St. Clair Herb Company, East St. Louis, Ill. Shipped Oct. 17, 19 and 24, 1942. Composition: Douche—essentially a small amount of ferric sulfate and lesser amounts of compounds of magnesium and calcium, unnamed plant extractives and water; No. 9 Herb Tea—chiefly small amounts of extracts of plant drugs, salicylic acid and water; No. 10 Herb Tea—essentially small proportions of plant drug extracts, salicylic acid and water. Douche declared misbranded because label falsely represented it as efficacious to build health and cure or prevent infections and growths of the female organs. Cruez No. 9 Herb Tea and Cruez No. 10 Herb Tea misbranded because falsely represented to cure or prevent gout, rheumatism, impaired sexual vigor and disorders of the blood, kidneys and bladder.—[*D. D. N. J., F. D. C. 934; October 1944.*]

Mennen Antiseptic Oil.—Mennen Company, Newark, N. J. Shipped Feb. 16, 1942. Composition: a yellow, perfumed, saponifiable oil containing small amounts of hydroxyquinoline, chlorobutanol, hydroquinone and benzoic acid. Misbranded because of these false and misleading label claims, among others: "It has equal antiseptic and germicidal powers to the commonly used ammoniated mercury ointments. . . . Meets the widespread demand of hospitals, physicians, nurses and mothers . . . offers protection against infection."—[*D. D. N. J., F. D. C. 926; October 1944.*]

Paracelsus.—American Biochemical Corporation, Cleveland. Shipped May 22, 1942. Composition: chiefly potassium chloride, sodium phosphate, chloride and bicarbonate, magnesium sulfate, calcium lactate and lesser amounts of other chemical salts. Misbranded because of false label representations regarding mineral content and efficacy as a dietary supplement, a body builder, a tonic and a remedy for disorders due to dietary deficiencies, particularly in minerals; also because recommended for arthritis, neuritis, influenza and phlebitis.—[*D. D. N. J., F. D. C. 925; October 1944.*]

Presto for Blackheads (Presto Stick).—McJohn Cosmetic Company, Hollywood, Calif. Shipped July 21, 1942. Composition: essentially ground pumice and titanium dioxide, in a hydrated waxy base. Misbranded because falsely represented on label to remove blackheads.—[*D. D. N. J., F. D. C. 942; October 1944.*]

SNL (Suffer No Longer).—Mrs. Cora Lee Wiley, doing business as the SNL Company, Adel, Ga. Shipped May 27 and July 19, 1941. Composition: essentially iodine, boric acid, organic silver compound, iodide, sulfate, and a small amount of a magnesium compound, with alcohol, glycerin and water. Misbranded because label falsely represented that SNL would, among other things, relieve female and abdominal troubles, protect women against every germ, including that of tuberculosis, and enable the user to build health, happiness, strength and beauty and increase length of life.—[*D. D. N. J., F. D. C. 932, October 1944.*]

Tritolac.—Thomas E. Collins Company, San Francisco. Shipped July 15, 1940. Composition: essentially embryonic tissues closely resembling wheat germ, with something similar to spray-dried skim milk, and an appreciable amount of wheat bran particles. Misbranded because label falsely represented that product would cure or prevent disease, stimulate rundown or nervous persons, help to correct functional and degenerative changes in the entire nervous system and similar changes in the body organs and tissues, and benefit some other disorders.—[*D. D. N. J., F. D. C. 929; October 1944.*]

Tuberculosis Compound.—Emile Carpentier, trading as Dr. Emile Carpentier, N.D., Hillsdale, N. J. Shipped Oct. 1, 1941. Composition: essentially plant material, sugars, a fatty substance and water. Misbranded because of false and misleading label representations that product would cure in from six weeks to six months tuberculosis in various parts of the body as well as many other disorders, and contained tested exhilarating and vitalizing herbs, roots and ingredients which would eliminate the germs ("bugs") of tuberculosis. Following a verdict of guilty by a jury in the district federal court of New Jersey, Carpentier was sentenced to a year in the custody of the Attorney-General, but sentence was suspended and defendant was placed on probation for five years.—[*D. D. N. J., F. D. C. 931; October 1944.*] In 1933 and 1940 the Post Office Department debarred from the mails the fraudulent "consumption cure" business that Carpentier had operated under various names, including those of himself and his wife. In 1938 he was fined $15,000 in a federal court for defying an order of the Federal Trade Commission to cease representing that the "T. B. Compound" put out under his name had therapeutic value.

Vita Malt with Natura Calcium Compound.—Natura Remedy Company, Los Angeles. Shipped May 23, 1941. Composition: Vita Malt, essentially a malt extract, with small amounts of saponifiable oils, water and sodium benzoate; Natura Calcium Compound, sodium bicarbonate and calcium salts. Vita Malt misbranded because label falsely represented that product would reduce body weight and benefit a variety of disorders, such as anemia, nervousness, sleeplessness, glandular disturbances, lack of appetite, infections and arthritis. Natura Calcium Compound misbranded because represented as effective in treating colds and la grippe.—[*D. D. N. J., F. D. C. 945; October 1944.*] Vita Malt also misbranded under the provisions of the law applicable to foods, as reported in *F. N. J. 5788.*

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Opticians' Practice Act (Connecticut): Application to Operation of Optical Store Not under Supervision of Licensed Optician and Filling Prescriptions of Licensed Physicians.—Chapter 161a, General Statutes, Connecticut, Cumulative Supplement, 1935, provides for the regulation of opticians and optical establishments. Section 1161c of that chapter reads as follows:

> No optical glasses or kindred products or other instruments to aid vision shall be sold at retail except under the supervision of a licensed optician and in a licensed optical establishment, office or store. Any optical establishment, office or store, not under the supervision of a licensed optician, may sell eyeglasses upon a permit from said commission to so sell, provided such permit shall specify the articles which may be sold. Said commission shall have the power to issue such a permit.

The defendant conducted an optical retail store without the supervision of a licensed optician, nor did he possess a permit from the commission of opticians (the licensing agency created by the chapter just referred to) as apparently required by the section quoted. He operated, so he claimed, by selling "optical instruments" at retail only on the prescription of a licensed physician in his employ. Neither he nor any person in his employ, other than the licensed physician, attempted to measure the vision of the eye. He was convicted on an information that charged in three counts violation of the section quoted. The first count charged that he conducted an optical store without a permit; the second, that he conducted the store without the supervision of a licensed optician; and third, that he sold optical instruments at retail in violation of the section. He appealed to the Supreme Court of Errors of Connecticut.

The defendant claimed (1) that the statute for the violation of which he was convicted was invalid and (2) that he did not violate that section because he sold only on the prescription of his physician employee and did not attempt to measure vision. The defendant's claim, said the Supreme Court of Errors, that he did not violate the statute may be stated broadly to be that chapter 161a, supra, exempts optometrists from its provisions and that chapter 161, supra, relating to optometrists, excepts physicians from its provisions, and hence the optical instruments sold on the prescription of a licensed physician employed by him, with no attempt on the part of the defendant to measure vision of the eye, did not constitute a violation of the statute quoted. The short answer to this claim is that physicians prescribe and opticians fill prescriptions and that chapter 161a (the opticians' practice act) for the violation of a section of which he was convicted relates to the filling of prescriptions and not to the making of them. One of the statutory definitions of an optician is "one . . . skilled in the technique of producing and reproducing ophthalmic lenses and kindred products and mounting the same to supporting materials" (section 1175e). Such mechanical skill is not required of a physician nor is it a tenable claim that the legislature presumed that a physician would have such skill. It is apparent that the supervision of a physician in the defendant's store did not comply with the provision of the statute quoted requiring the supervision of a licensed optician.

The first count of the information charged the defendant with conducting an optical store without a permit from the commission of opticians. Admittedly, said the court, the defendant sold optical instruments without a store permit. He claimed, however, that that part of the statute quoted requiring a store permit is unconstitutional as an unlawful attempt to delegate power to the commission of opticians. Section 1167c (a section of the opticians' practice act) gives the commission authority to make regulations concerning the granting of permits to optical departments. Section 1162c provides that the commission shall grant permits "upon satisfactory evidence to said commission that such . . . store is being conducted in accordance with the regulations of said commission." The only suggestion as to the character of such regulations is that they must not be inconsistent with law and must be in keeping with the provisions of chapter 161a. Nowhere in the chapter are there any provisions as to the method of conducting the business which would limit the regulations. No sufficient guide for the exercise of the discretion reposed in the commission has been set up. No standards for the issuance of permits have been specified. As was said in *State v Stoddard,* 126 Conn 623, 13 A (2d) 586:

> A legislature, in creating a law complete in itself and designed to accomplish a particular purpose, may expressly authorize an administrative agency to fill up the details by prescribing rules and regulations for the operation and enforcement of the law. In order to render admissible such delegation of legislative power, however, it is necessary that the statute declare a legislative policy, establish primary standards for carrying it out or lay down an intelligible principle to which the administrative officer or body must conform, with a proper regard for the protection of the public interests and with such degree of certainty as the nature of the case permits, and enjoin a procedure under which by appeal or otherwise, both public interests and private rights shall have due consideration.

The necessary standards on which the commission is to base its regulations as to the suitability of optical establishments entitling them to a permit are not established by chapter 161a. The court accordingly held that the provisions of the statute quoted with respect to store permits are invalid.

The second and third count of the information under which the defendant was convicted charged that he had conducted his store without the supervision of a licensed optometrist and that he had sold optical instruments at retail in violation of the section quoted. The defendant claimed in this respect, that there was no adequate provision made in the opticians' practice act for the licensing of opticians and that therefore the absence of a licensed optician in his store would not subject him to criminal prosecution. The preliminary requirements in the opticians' practice act, said the court of errors, with respect to examining applicants for a license to practice as opticians are reasonably certain. Section 1164c provides that no person shall be admitted to take an examination until he shall have satisfied the commission that he is 21 or more years of age, is of good moral character and has had four years' practical experience in the business, or the equivalent in a reputable college of opticians from which he has received a diploma. The section, however, purports to deal with two classes: those already engaged in the occupation of optician at the time of the passage of the act, and others. This distinction was apparently overlooked in providing for an examination, for the final sentence in the section requires as a condition precedent to the granting of a license that "application for such license shall be made to the commission, together with satisfactory proof of such knowledge, skill, technique and ability on or before March 1, 1936." As the section reads, no person may be granted a license without compliance with the requirement. The effect of this, restricting as it does the granting of licenses to persons possessing the requisite qualifications applying before March 1, 1936 was obviously not that intended by the legislature. A legislative intention, not expressed in some appropriate manner, has no legal existence. We are not at liberty to speculate on any supposed actual intention of the legislature, which can be shown only by its vote. Reasonable certainty is a prime requisite in a statute and its absence invalidates the statute. This rule is of greater insistence when a criminal prosecution, as here, is involved. In the opinion of the court this section in this respect was invalid for uncertainty.

The judgment of conviction was set aside and the cause was remanded to the lower court with direction that the defendant be acquitted.—*State v Van Keegan, 42 A (2d) 352 (Conn, 1945).*

Hospitals: Nursing Home Not Hospital Under Hospitalization Policy.—The plaintiff and his wife sued to recover for hospital expenses incurred by the wife, the suit being based on a policy of hospitalization insurance issued by the defendant insurance company. From a judgment in favor of the plaintiff, the defendant appealed to the court of civil appeals of Texas.

The plaintiffs alleged that Mrs Givens, after vainly seeking admission to a regular hospital in Los Angeles, was admitted, through the request of a Dr Wilson to the nursing home of Mrs Daisy Wharton in the same city. At the time of her admission to the nursing home she possessed a hospitalization policy issued by the defendant which apparently agreed to remunerate her for certain hospital expenses which she might incur. It was stipulated that the word "hospital" as used in the policy, meant

> an institution conducted for the regular reception and treatment of the sick, rendering services and facilities commonly and generally recognized and accepted as hospital services and facilities but shall not include facilities provided in a doctor's office or clinic used merely in the routine treatment of patients and not generally recognized as hospital facilities.

Mrs Givens testified that while she was in the nursing home she was regularly visited and treated by her physician and that the nursing care included private room, bedside attention, special diet and meals. She testified further that she had been a patient at Baylor Hospital, Dallas, Texas, prior to this time and afterward at St Paul's Sanitarium, with the same ailment, and was rendered the same service as was afforded at the nursing home. Mrs Givens admitted on cross examination however, that she could think of no facilities or services which she received at the nursing home but would not have received in her own home if she had hired a private nurse to take care of her there. Mrs Wharton testified that she was a private nurse, that the nursing home was her private home and that hospitals were not permitted in the residential section of Los Angeles where she lived, that her establishment was in no sense a hospital, sanitarium or sanatorium, that her nurses' home would not qualify as a hospital in that it did not have any of the following facilities usually found in hospitals: x-ray equipment, laboratory equipment, sterilization rooms, operating rooms, and drug and chemical laboratories and dispensaries.

The court of appeals said that the contract between the parties provided for the furnishing of services by a hospital, held that the terms of the policy were not ambiguous in defining a hospital, and concluded that the nursing home of Mrs Wharton was not such an institution. Accordingly the judgment in favor of the plaintiffs was reversed.—*Employers Casualty Co v Givens et ux, 190 S W. (2d) 155 (Texas, 1945)*

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Oral.* Chicago, May 5-12. Sec., Dr Paul Titus, 1015 Highland Bldg., Pittsburgh.

AMERICAN BOARD OF OTOLARYNGOLOGY: Chicago, May 22-25. Sec., Dr Dean M Lierle, University Hospital, Iowa City, Ia.

AMERICAN BOARD OF PEDIATRICS: *Written.* Locally, March 22. *Oral.* Cleveland, April 27-28 and San Francisco, July 1-5. Sec., Dr Lee F Hill, 3309 Forest Ave., Des Moines, Ia.

AMERICAN BOARD OF RADIOLOGY: Chicago, Nov 27 to Dec 1. Final date for filing application is Sept 1. Sec., Dr B R. Kirklin, Mayo Clinic, Rochester, Minn.

AMERICAN BOARD OF SURGERY: *Written. Part I.* Various centers, October. Final date for filing application is July 1. Sec., Dr J S Rodman, 225 S 15th St., Philadelphia 2.

AMERICAN BOARD OF UROLOGY: *Oral.* Chicago, February, 1947. Final date for filing application is Nov 15. Sec., Dr Gilbert J Thomas, 1409 Willow St., Minneapolis 4.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1936 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Uterine Bleeding and Extragenital Disturbances. I. L. Frank.—p. 787.
Congenital Hemolytic Anemia: Review of Progress. I. J. Wolman.—p. 798.

Coarctation of Aorta Associated with Pregnancy.—Kinney and his associates report the first instance in which a complete anatomic diagnosis was made antemortem in a case of this sort. A pregnant woman aged 23 died suddenly as the result of rupture of an acute dissection of a coarcted aorta into the pericardium. The onset of sudden severe pain in the throat and the back of the neck, which also involved the upper part of the back and the left arm, directed attention to the possibility of a vascular accident. The routine examination, which revealed absent femoral and abdominal pulsations, quickly focused attention on the possibility of coarctation of the aorta. This readily explained the basal systolic murmur and led the author to listen to the interscapular region, where the same murmur was audible. Confirmatory evidence was obtained when a pulsating artery was detected in the left midback, and blood pressure could not be measured in the legs. The clinical diagnosis was made even though the x-ray examination at first overlooked changes in the ribs. After the diagnosis of coarctation had been established, the explanation for the symptoms appeared to be rupture of the aorta.

Penicillinase in Body Fluids from Patients Being Treated with Penicillin.—Dowling and Hirsh investigated the effect of blood culture medium on penicillinase. They found that penicillinase does not lose its ability to neutralize penicillin when both substances are added to veal infusion broth and kept at incubator, room or refrigerator temperature for four weeks. In the concentrations in which it is used for this purpose, penicillinase has no inhibitory effect on the growth of bacteria. Among 26 patients from whom parallel cultures were taken, with and without penicillinase, the presence of penicillinase in the culture medium gave information on 12 patients which was not obtainable or which was delayed or doubtful when the culture was taken without the benefit of penicillinase. Among 186 specimens of body fluids obtained from patients under treatment with penicillin, cultured in parallel with and without penicillinase in the culture medium, 36 showed better growth in the medium containing penicillinase. It is recommended that penicillinase be used routinely in cultures of body fluids obtained from patients under treatment with penicillin.

Iodine, Thiourea and Desiccated Thyroid in Hyperthyroidism.—In the treatment of 12 patients with hyperthyroidism Danowski and his associates administered 5 to 15 drops daily of strong solution of iodine. After the remission with iodine therapy had reached its maximum, thiourea was started in doses varying between 0.05 and 0.28 Gm. once daily. Patients whose level of serum precipitable iodine fell below normal received 0.06 Gm. of desiccated thyroid daily as well. In some instances iodine medication was later discontinued. The serum precipitable iodine, the basal metabolic rate, the body weight, the pulse rate, erythrocyte and leukocyte counts, the size of the thyroid gland and the general clinical condition were carefully followed. Preliminary iodine medication diminished the severity of the hyperthyroidism for a time in most of the patients but failed to produce a complete and lasting remission. Administration of thiourea as well as iodine resulted in a complete disappearance of the signs of thyroid overactivity and depression of serum precipitable iodine to normal or subnormal in 11 out of 12 instances. In the patients who required and were given maintenance doses of desiccated thyroid the concentration of precipitable iodine in the serum promptly returned to normal. Evidently thiourea in daily doses of 0.280 Gm. can produce a satisfactory sustained remission in cases of hyperthyroidism which have previously been brought into partial remission by iodine medication alone. This fact disposes of any theory that previous treatment of the hyperthyroidism with iodine seriously interferes with the action of thiourea. Cases of toxic adenoma and of diffuse goiter both respond.

Postsalpingectomy Endometriosis in Laparotomy Scars.—According to Sampson the pathogenesis of endometriosis in laparotomy scars depends on the type of the original operation and the anatomic conditions or relations resulting from it. The author has encountered 17 patients with laparotomy scar endometriosis in the gynecologic service of the Albany Hospital. In a case in which salpingectomy had not been done the scar endometriosis followed a myomectomy. The scar endometriosis was derived from the mucosa of a tubal stump by continuous invasion in 10 specimens. It probably arose in a similar manner in 3 others. In 2 additional specimens such an origin could not be excluded. Transplantation endometriosis was possibly present in 3 scars. In the remaining 2 cases two separate foci of endometriosis were found in each scar, one of which arose by continuous invasion from the mucosa of a stump. The other possibly developed as a result of transplantation. The postsalpingectomy scar endometriosis has resulted from the outgrowth of sprouts of the mucosa of the tubal stump. These, as tubules, invade the tissues about the stump, usually the uterine cornu. From here they spread to the portion of the laparotomy scar attached to that cornu. Injecting the uterine cavity with colored gelatin has been helpful in the study of these cases, in 12 of which the uterine cavity was injected. Gelatin was found in the scar endometriosis in 8 of these, thus demonstrating the continuity of their tubules with the uterine cavity. The most dramatic demonstration of the value of the injection method in ascertaining the pathogenesis of postsalpingectomy scar endometriosis was the presence of gelatin in the tubules of a scar in which the only contact with the uterus was the remains of a drainage tract 7 cm. long. This specimen likewise showed the ability of müllerian tissue to extend itself by continuous growth and invasion for a long distance. The mucosa of the left tubal stump had grown out through the end of the stump into the lumen of the drainage tract, entirely lining it with columnar epithelium. The drainage tract ended, as such, at the base of the scar. Here sprouts had arisen from its mucosa and had invaded the scar actually to the skin epithelium. The total distance traveled by the continuous extension and invasion was 11 centimeters. The ectopic mucosa, which can be shown to have had its origin in the mucosa of a tubal stump and to have grown from it by continuous invasion, may not only retain the structure of the tubal mucosa but may also assume the structure and function of the uterine mucosa, including its reaction to menstruation and pregnancy, thus producing true endometriosis. Tubules play the more prominent role in some specimens of scar endometriosis, and glands in others; they are the leaders of the invasion. A tubule is a müllerian gland without appreciable stroma about it, and a gland is a müllerian tubule clothed in stroma.

Sweat Gland Tumors of Vulva.—Novak and Stevenson report 15 cases of sweat gland tumors of the vulva. These appear as small and innocent looking growths on or near the vulva, but to one not familiar with their microscopic appearance the microscopic picture is apt to be rather startling and perhaps lead to the diagnosis of adenocarcinoma. In only 1 case in the literature, that of Eichenberg, has there been unimpeachable evidence of malignant change, both clinical and microscopic. All other cases have been clinically benign and all have been cured by simple excision. It is possible that some instances of the rare primary adenocarcinoma of the vulva may be of sweat gland origin. Such an origin is difficult to establish. The ages of the patients with vulvar hidradenoma observed by the authors varied between 28 and 67 years. The most common location of the lesion is on the labia majora, and next most common is in the paralabial skin or perineum. In a few cases the growth has been situated on a labium minus. This is of interest, since many histologists believe that sweat glands are not normally found in the lesser labia. This may be true of the ordinary sweat glands, but one cannot be so sure as to glands of the apocrine type, which are rather closely related to sebaceous glands, of which there are enormous numbers in the labia minora. The authors suggest that the apocrine gland derivation of the vulvar sweat gland tumors may have been overemphasized. All of the 15 patients observed by them were white, in spite of the fact that a large proportion of clinic patients are Negroes. The lesion is always small, usually not over 1 cm. in diameter. There is no pain, and frequently the nodule is not noticed by the patient. There is considerable variation in the microscopic appearance of these hidradenomas.

Curability of Granulosa Cell Tumors.—Jones and Te Linde point out that the collection of adequate statistics on the malignancy of the granulosa cell tumor is difficult, as the incidence of late recurrence in this tumor group makes five or even ten year follow-up studies inadequate. This fact has been brought to the attention of the authors by the recent return of 3 patients, all having recurrent granulosa cell tumors fifteen, sixteen and nineteen years respectively after their original operation. All 3 patients have died eighteen, twenty and twenty-one years respectively following the removal of the primary tumor, in spite of the fact that the tumors were well encapsulated and showed no evidence of metastasis or implantation at the original operation. One case recurred in spite of a bilateral salpingo-oophorectomy and a hysterectomy. One case with widespread inoperable abdominal metastases responded well to high voltage x-ray therapy over a period of three years, but a subsequent recurrence of the growth proved refractory to treatment. Total urinary estrogen values were not extremely high in 2 cases but within the range of values for normal women. The values were well above those usually found in this laboratory for postmenopausal women, into which age group all 3 patients fell at the time of recurrence. All 3 cases exhibited clinical signs of estrogenic activity on recurrence of the tumor.

Effect of Chronic Fluorine Intoxication on Bones and Teeth.—Bauer kept a bitch and puppies between the ages of 28 and 98 days on a fluorine diet. The bitch received 0.4 Gm. of sodium fluoride daily; some of the puppies were suckled by their fluorine poisoned mother, while others were fed mother's milk for four weeks and afterward received food containing 0.1 to 0.2 Gm. of sodium fluoride. Chronic fluorine intoxication of puppies produced extensive systemic changes in the bones and the developing teeth. The intensity depended on the age of the animal, the dose and the duration of the administration of sodium fluoride. Small doses of fluorine administered over a long time and started at an early age resulted in a dense periosteal bone formation. In puppies fed exclusively the milk of their fluorine poisoned mother, bone changes were observed prior to changes of the tooth buds. The cells of the periosteum were apparently stimulated to assume osteoblastic function even before the enamel forming cells were affected. That in these experiments changes in the bones and the developing teeth could not be prevented or alleviated by an antirachitic diet and that calcification of a startling amount of periosteal and endosteal bone occurred in spite of continued administration of fluorine suggest that the pathogenesis of the bone and tooth lesions in rickets and fluorosis differs. The enzymatic and protoplasmic action of fluorine produced rachitic-like changes in the bones and the dentin of puppies, but its effect on the bones of the older dogs and the enamel in general differed from rickets. These experimental studies and recent observations on dental fluorosis in children and adults associated with bone changes indicate the necessity of a thorough roentgenographic examination of the skeleton of children showing "mottled enamel" in fluorine areas in this country.

Intravenous Obstetric Anesthesia.—Allen's impression is that the infusion of procaine should usually not be begun in the earliest stage of labor. In the second stage, when contractions are stronger and the suffering greater, the analgesic effect is most welcome. With intravenous procaine infusions two grades of obstetric analgesia are obtainable, provided rare cases of hypersensitiveness are excluded by tests. Small dosage, not sufficient to cause dizziness or other subjective symptoms, can dull the pains especially during the second stage of labor. This effect is interpreted as being dependent wholly or chiefly on the peripheral nerves. It fails to give much relief during third stage delivery and subsequent repair operations. The advantages are the considerable alleviation of suffering with convenience and complete safety. Larger dosage, by an apparent central action, induces a state of dim consciousness in which the patient is more or less unresponsive but retains some awareness and memory of events. Touch sensations may persist, but anesthesia, in the sense of absence of pain, can be maintained during delivery and necessary operations. The only difficulty encountered thus far has been the occasional liability to convulsions. These have not been disastrous and can apparently be prevented by preliminary administration of barbiturates. The advantages are the convenient, flexible and rapidly controllable anesthesia, the noninterference with uterine contractions in the active stage and the almost immediate recovery without headache, nausea, disorientation or other after-effects. The apparent safety for both mother and child still requires confirmation by larger experience.

Thrombin (Topical) in Transurethral Resection of Prostate.—Bandler and his associates employed thrombin (topical) in 50 resections of the prostate for hypertrophy or carcinoma and have compared their results with 50 resections immediately preceding in which bladder irrigations were used in the postoperative management. Results with thrombin (topical) were very satisfactory. Postoperative bladder irrigations were completely eliminated. Postoperative bleeding was decreased in amount and duration. The inlying catheter could be removed earlier, and there were fewer postoperative hemorrhages when thrombin was employed than when irrigations were relied on in the postresection period. The use of 10,000 units was found to be more efficacious than the 5,000 unit preparation. There were no toxic effects nor other disadvantages in the use of thrombin.

Intracardiac Blood Transfusion.—Iokhveds reports 2 cases of severe shock and massive hemorrhage in which isotonic solution of sodium chloride, glucose and blood were used for reviving intracardiac blood flow. The first patient was a Red Army soldier aged 34 to whom blood transfusion through a needle inserted into the right ventricle had restored consciousness. Severe myocardial damage was probably responsible for death that occurred two and a half hours later. In spite of the flabbiness of the myocardium, the needle, which was present in the heart for about fifteen minutes while the heart was contracting, had left only a minute puncture. The second patient, a soldier aged 18, was given an injection of blood and salt solution into the left ventricle. It was believed that the contracting force of the recently revived heart and the pressure of the solution being injected would be insufficient to overcome the resistance of the capillary network in the lungs, so that only insignificant amounts would reach the left side of the heart. Injection of these solutions directly into the left ventricle causes even the first and comparatively weak contractions of the heart to reestablish the blood supply to the vitally important brain centers, thus providing an antishock effect. In addition, the increased volume output of the left ventricle independently improved the coronary blood flow. The patient improved rapidly. The intracardiac injection was made eight to ten seconds after all clinical symptoms of death had appeared. When blood and other liquids are to be transfused into the right chamber, the needle should be inserted into the lower part of the fourth left intercostal space, one fingerbreadth from the left margin of the sternum. The left ventricle will be entered when the needle is inserted in the same interspace and 2.5 to 3.0 cm. to the left of the left margin of the sternum. The needle should be 7.0 to 8.0 cm. long, its inner diameter 0.6 to 0.8 mm. If the initial 80 to 100 cc. of blood or other liquid is ineffective, further transfusion will be without effect.

Carbohydrate Metabolism and the Skin.—Urbach and Lentz review the results of studies on patients with various skin diseases with and without diabetes and on various species of animals. While in human beings the free sugar content of the skin is only two thirds of that of the blood, the skin of many species of animals contains more free sugar than their blood. Therefore results obtained in investigations on animal skin are not applicable to conditions in human beings. The sugar level of the skin is dependent on the diet. This explains the efficacy of a low carbohydrate diet in diabetic dermatoses. A diet high in fat results in a distinct decrease in the sugar content of the skin, while that of the blood remains stationary. A blood sugar tolerance test is indispensable in order to determine whether or not a dermatosis is of diabetic origin. The type of curve indicates whether a pathologic reaction is brought on by excessive mobilization of dextrose by an imbalance in the sympathetic or the endocrine system or by a decrease in the capacity to assimilate sugar, i. e. by a lowered sugar tolerance, as in diabetes. In pancreatic diabetes the ratio between the fasting skin sugar and the blood sugar is increased. The sugar content of the skin is almost doubled after a sugar tolerance test. It takes the skin sugar level five hours or longer to return to normal. The prolonged storage of sugar in the skin may perhaps explain its great susceptibility to infection in diabetes. In mild diabetes with cutaneous manifestations the ratio of skin sugar to blood sugar is relatively high (65.7 per cent), whereas the ratio is rather low in cases without cutaneous symptoms. Extensive inflammation or infection of the skin can produce a metabolic disturbance of the carbohydrate metabolism which is of peripheral origin and in no way connected with pancreatic diabetes. These facts, together with the presence of cleavage and end products of the intermediary carbohydrate metabolism in the skin, as well as the presence of glycolytic enzymes and the fact that insulin-like substances can be derived from cutaneous tissue, would seem to underscore the important role played by the skin both in intermediary carbohydrate metabolism and as a storage organ.

Esophageal Lesions Associated with Acrosclerosis and Scleroderma.—Olsen and his associates reviewed the records of all cases at the Mayo Clinic from 1930 to 1943 inclusive in which diagnoses of scleroderma or acrosclerosis had been made with respect to the occurrence of esophageal symptoms or signs. In 36 of approximately 350 cases of scleroderma or acrosclerosis dysphagia occurred or lesions of the esophagus were demonstrated. In approximately 10 per cent of these cases complaints referable to the esophagus were made. The most common complaint was dysphagia. Frequently there was also substernal burning after meals, especially when the patient was lying down. Positive roentgenographic or endoscopic evidence was demonstrated in 18 cases. Dilatation of the esophagus similar to that seen in cardiospasm was observed in 7 cases, and hiatal hernia with intrathoracic stomach was demonstrated in 9 cases. In 2 cases sclerodermic changes were demonstrated in the esophageal wall. In acrosclerosis symptoms of Raynaud's disease are present prior to the dermatologic changes or coincident with them. Thirty-three of the 36 patients who had esophageal symptoms presented the clinical syndrome of acrosclerosis. All the 18 patients for whom conclusive roentgenographic or endoscopic evidence was obtained had acrosclerosis. Sclerodermic changes in the connective tissues of the esophagus are chiefly responsible for the esophageal disturbances, which are extremely uncommon in Raynaud's disease per se. Reduction or absence of muscular activity in the wall of the esophagus and shortening of the esophagus apparently result from sclerodermic involvement. Disturbances of the autonomic nervous system may play some part in the causation. Clinical diagnoses of cardiospasm and hiatal hernia of the short esophagus type are made most frequently in these cases. Stenosis of the lower part of the esophagus and esophagogastric junction may occur with hiatal hernia as the result of chronic inflammation of the lower part of the esophagus. This inflammation is the result of incompetence of the cardiac sphincter with regurgitation of gastric secretions. Treatment of esophageal lesions of acrosclerosis consists in passage of sounds over a previously swallowed thread. Fairly satisfactory results have been obtained.

South American Trypanosomiasis.—Although Chagas disease has been considered as one limited to South or Central America, it could become endemic in the United States. Naturally infected triatomas (the insect vector) and ones capable of acting as vectors have been found in Arizona, California, Florida, New Mexico, Texas and Utah. Moseley and Miller observed Chagas disease in 2 American soldiers. Both were infected by the trypanosome in Panama. In contradistinction to the cases previously reported from Panama the infection gave rise to a serious illness in both soldiers. These are the first 2 instances in which the infection has been diagnosed in other than native born inhabitants in this country. Serial electrocardiograms were made, and the cardiac manifestations of the disease were studied in 1 case. Articular symptoms and signs may occur as a manifestation of this disease and these and many of the other features of acute Chagas disease may closely simulate rheumatic fever. Lymphocytosis appears to be a laboratory finding of clinical significance in Chagas disease. In the treatment of these 2 cases antimony was of therapeutic value.

Resection of Lung in Pulmonary Tuberculosis.—Brantigan says that, if the contralateral lung is free of disease, *pulmonary resection appears to be the best treatment after the* occurrence of irreparable damage, such as bronchial stenosis, bronchial disease with or without ulcerations not responding to bronchoscopic treatment and after an unsuccessful thoracoplasty. *Pulmonary resection is the only form of treatment that* can be used effectively when pneumothorax or phrenic paralysis, with or without pneumoperitoneum, does not control disease at the base of the lung, a cavity against the mediastinal surface in the lower half of the chest, or a cavity in the middle portion of a lung. Criticism might be justified when a lobectomy of the upper lobe is elected as a method of choice instead of thoracoplasty. He reports 9 cases in which lobectomy was done, with 1 fatality. In 5 of the 9 cases endobronchial disease existed. Pulmonary resection for tuberculosis is a relatively safe operation. The late end results are as yet unknown. *As long as the postoperative condition is an improvement over* the preoperative one, definite benefit has been achieved even though the disease is not cured.

Value of Protein in Surgical Repair.—Co Tui stresses that proteins are essential to wound healing, the maintenance of tissue integrity and expeditious convalescence. Protein deficiency endangers all three. A patient can become protein deficient as a result of inadequate intake and increased nitrogen output or a combination of these two factors. Decreased intake may be due to the patient or to neglect on the part of the attending staff. Increased output may be due to increased metabolic loss and to the loss through exudates. The ceiling of nitrogen intake in natural food is naturally low, and consequently natural food is often inadequate to replenish the increased protein loss in disease and injury. Studies in cases of burns and of postoperative gastrectomy, cholecystectomy and herniotomy suggest that convalescence can be shortened, strength and weight conserved by full caloric and nitrogen replacement immediately postoperatively and that there may be a critical range of nitrogen intake for each disease category. The protein hydrolysates are indispensable in many disease conditions and can be used with greater elasticity than natural food. In the course of study on the value of protein hydrolysates a new treatment of peptic ulcers has been evolved. *Protein hydrolysates for clinical use must fulfil* a number of criteria, and clinicians using them must be quantitatively minded. The nutritional status can be studied by four methods: (1) the nitrogen balance, (2) the plasma protein curve, (3) the body weight curve and (4) the bedside ergograph.

Fenestration Operation.—Sullivan's experience with the fenestration operation was gained in the treatment of 410 cases. The degree of improvement in hearing which is obtained and maintained as a result of plastic reconstruction of the auditory mechanism in an otosclerotic ear is in direct proportion to the exactitude and perfection with which each step in this technic is carried out. Complete rehabilitation for social and economic contact as a result of restored hearing was accomplished in 246 of his 410 cases. Partial rehabilitation for social and economic contacts was accomplished in 17 cases. The hearing was not improved and remained at the preoperative audiometric decibel level in 21 cases. The hearing was depressed to a decibel level lower than the preoperative one in 15 cases. There were 19 cases in which the fistula had closed and the hearing reached its preoperative level. The loudness balance test gives more information than any of the others. In this test, a sound is fed every one and one-half seconds to one of a pair of matched earphones on the patient's ear. If the ears are not the same the sound is selectively adjusted on one of the ear phones until the loudness is equal; that is, the loudness is balanced. The difference between the two voltages measures the difference in the loudness sensitivity of the two ears. The balance is carried out in steps from threshold level up to the limit of the patient's tolerance, where discomfort or pain occurs. In clinical otosclerosis cessation of the progress of deafness can be obtained by the establishment of a permanent labyrinth fistula. To obtain a lasting improvement, a second condition is required: the adaptation to this fistula of a new tympanic system as amplifier of the aerial sound vibration. The duration of the functional benefit depends on the permanence of the anatomic modification.

Tietze's Syndrome.—The syndrome of nonsuppurative and nonspecific but painful swelling of rib cartilages was first described by Tietze in 1921. All of Geddes' 22 patients had a concomitant respiratory infection. In some the onset of the respiratory infection antedated the chest pain; in others it was coincident; in still others the respiratory symptoms followed in one or two days. In the cases of long duration there was a strong tendency to recurrence of tenderness with each fresh "cold." All the cases occurred in autumn and winter. The age incidence varied from 19 to 40 years. All were well nourished. Altogether 28 cartilages were involved in the 22 patients. The second left and the second right costal cartilages were most frequently involved, but apparently any of the costal cartilages can be involved. The course is variable and often prolonged. The disability produced is minor, not necessitating hospitalization, but may be very annoying and in most cases necessitates light duty for weeks. The cause is unknown. There is no reason to suspect dietary deficiency. The association with respiratory disease is invariable. Tuberculosis and syphilis were ruled out. When patients present themselves with thoracic pain the possibility of Tietze's syndrome should be borne in mind.

Caloric Intake and Blood Sugar in Sarcoma in Mice.—Eight groups of 40 strain C mice each were placed on diets that varied in their content of calories, protein and fat. Half of the groups were allowed a caloric intake of 9.3 calories per mouse daily, and the other half were restricted to 5.7 calories per mouse daily. The groups were further divided in such manner that the level of protein was either high or medium and the amount of fat either medium or low. After the mice had been stabilized on their diets for fifty days, each was injected subcutaneously with 200 micrograms of 3,4-benzpyrene in 0.2 cc. of corn oil. A comparison was made between caloric consumption, tumor formation and the level of blood sugar. The mice on nonrestricted diets were heavier, the blood sugar tended to be higher than in those whose caloric intake was restricted, and the development of sarcomas was facilitated in the mice that were relatively hyperglycemic. Although the evidence indicates that under certain conditions the development of neoplasms is favored in animals with a somewhat elevated blood sugar, this in itself was not necessary for tumor formation, as was shown in the case of mice receiving a high caloric diet in which considerable carbohydrate was replaced by protein and fat. In this case the incidence of sarcomas was high, although the blood sugar level was not much different from that of the restricted mice.

Caffeine in Pathogenesis of Gastric Ulcer.—Giddings and his co-workers found that administration of 75 mg. of caffeine per kilogram of body weight by stomach tube to 26 cats daily for twenty-one days did not produce erosions or ulcers in the stomach. Injection of the same amount of caffeine daily intramuscularly in a mixture of beeswax and oil for the same length of time likewise failed to produce erosions or ulcers. Ulcers were produced in cats by caffeine only when the dose was large enough to kill the animal. Thirty-four albino rats were given 75 mg. of caffeine per kilogram of body weight by stomach tube over a period of eight to twenty weeks. In only 3 animals were there any alterations in the stomach that might be regarded as erosions or ulcers. The structural changes in these instances were microscopic. These experimental data do not offer valid reason for the conclusion that caffeine-containing beverages such as coffee or tea play a part in the pathogenesis of gastric ulcer in man.

Infectious Hepatitis in Wounded Men.—According to Snell and his associates infectious hepatitis has manifested itself as one of three clinical entities: epidemic jaundice, postvaccinal (yellow fever) hepatitis and homologous serum jaundice. Fatal cases of any of the three types have shown a common picture at necropsy, namely that of acute or subacute (yellow) atrophy of the liver. It appears probable that serum or blood containing the icterogenic agent might be responsible for certain clinical cases of hepatitis occurring in wounded men who had received these agents at the time of injury. The authors have seen 32 such cases, with recovery in 26; the six deaths occurred on an average of one week after jaundice was first noted. All patients had received blood or/and plasma at the time of injury and thereafter. Eight, including the 6 who died, developed symptoms of involvement of the central nervous system. The essential pathologic picture in the fatal cases was one of an acute autolytic process in the liver. The relatively high mortality in this series is believed to be due to nutritional factors secondary to the wounds which these men had received The prevention of fatalities in serum jaundice occurring in wounded men must begin with the maintenance of their general nutrition and the correction of protein and vitamin deficiencies. The use of dextrose intravenously becomes a necessity until vomiting and anorexia have subsided. The authors used amigen solution conjointly with the dextrose. Once the patient is able to take food, the standard high carbohydrate, high protein diet, low in fat, long employed in the treatment of hepatic disease, should be administered until functional hepatic tests indicative recovery.

Cardioesophageal Relaxation.—Berk says that cardioesophageal relaxation or incompetence of the cardiac sphincter is an abnormality in which contents from the stomach regurgitate freely into the esophagus. In the instance described the condition was diagnosed by roentgenoscopy and confirmed by esophagoscopy. The patient was a man aged 47. The cause of the condition is unknown. It is apparently not a clinical entity. The importance of cardioesophageal relaxation lies in its possible confusion with other conditions about the terminal esophagus, such as hiatus hernia, diverticulum, achalasia or cancer. It frequently gives rise to disturbing symptoms, chief of which are epigastric distress and lumpy sensation at the lower sternum. Regurgitation and the relationship of symptoms to position were prominent in the case reported. It is likely that cardioesophageal relaxation is frequently overlooked and that if the radiologist reviews his old plates he may see a globular mass of barium outlining the lower part of the esophagus and obscured somewhat by the shadow of the spine. Cardioesophageal relaxation can be diagnosed by fluoroscopy usually in the supine or Trendelenburg position, whereupon barium may be seen to flow passively into a dilated lower esophagus and gravitate back into the stomach when the upright position is assumed.

The Thymol Barbital Test.—Ancillary to an investigation of the thymol barbital test in experimental carbon tetrachloride intoxication, McCord and his associates examined the serum or spinal fluid of 712 hospital patients. In 168 specimens of a somewhat selected group, 20 reactors (12 per cent) were detected. There were 49 reactors, or 6.8 per cent, among the total of 712 patients. Liver damage was indicated in the greater number of reactors, but the validity of the test was lower than appraised by Maclagan. The observations made by the authors do not agree with the concept that this test constitutes a measure of the gamma globulin present. Gamma globulin in pure form does not provide positive results, while the phospholipins, apart from gamma globulin, consistently led to heavy reactions. In certain instances, in the presence of weakly positive determinations the addition of traces of gamma globulin (itself negative) enhances the degree of positivity. It appears possible that gamma globulin may enter or may influence the precipitation phenomenon without constituting the chief precipitate. Reactors were not detected among 30 presumably healthy workers. Among 52 chemical workers 4 reactors were encountered. The latter control group is not representative of industrial workers in general. Positive results at and above 4 thymol units suggest pathologic change with implications of the liver. The thymol barbital test is not a measure of liver function; instead it denotes disturbed liver metabolism.

Death of Aircraft Passenger Under Treatment with Pneumothorax.—Dowd reports that an airline passenger, a man aged 21 who had pulmonary tuberculosis and an artificial pneumothorax, wore an oxygen mask which functioned normally. The mask was applied at 7,000 feet altitude. In another ten minutes the altitude of 16,000 feet was reached. Two minutes later, and without prior evidence of illness, the passenger became unconscious. In spite of all efforts at treatment he remained unconscious up to his death twenty-eight hours later. Death most probably resulted from air embolism. The convulsions, vomiting and unconsciousness all point to some residual cerebral damage which one would expect from a focal cerebral lesion such as could occur in air embolism. There is also a possibility that the cerebral nervous system disturbance was due to prolonged cerebral anoxia which, because of mediastinal shift or mediastinal emphysema or both, brought about by increased pneumothorax induced by altitude, caused impairment of cerebral circulation with sufficient cerebral anoxia to cause an irreversible reaction and death. Patients with pneumothorax should not travel by air, or, if they must, the height at which they travel should be restricted to altitudes of 5,000 feet.

Electromyographic Studies in Poliomyelitis.—Kohn and his associates did electromyographic studies on 13 patients ranging in age from 7 to 33 years. The patients were tested from seven to eighty days following their admission to the hospital. It was found that most muscles paralyzed in poliomyelitis do not show electromyographic evidence of spasm while at rest and that spasm is not an ever present symptom in paralyzed muscles. In this series only 20 per cent of the involved muscles tested showed continuous and sustained potential changes even when passively stretched In cases showing inconstant discharges when stretched it was noted that the potentials appeared only with the initial stretching and disappeared even though the muscle was kept on tension. This led the authors to suspect that some of these potentials may have been due to a protective splinting of the muscle in response to the pain produced by the needle electrodes themselves. Such a possibility was tested by applying both surface electrodes and needle electrodes to the same muscle and stretching the muscle Potentials were picked up from this muscle by both types of electrodes. However, when the needle electrodes were removed and the muscle again stretched, potential changes were not detected. One of the most interesting findings was the evidence of disordered reciprocal innervation This phenomenon is understandable in view of the fact that pathologic changes in poliomyelitis are found not only in the anterior horn cells but in the posterior horn cells and posterior root ganglions as well. Since intercalated (internuncial) neurons are found in the posterior horns, these cell bodies are also involved in the disease process Disturbances in their function should be expected and clinically manifested by disordered reciprocal and cross innervation reactions. The simultaneous activation of agonist and antagonist corroborates a similar finding by Watkins and his associates. The additional finding of simultaneous activation of corresponding antagonist and agonist muscles of the opposite side tends further to support the concept of disorganization of the neuromuscular mechanism in poliomyelitis as one of the features of this disease.

Fatality in Electroshock Treatment.—Gralnick reports what appears to be the thirteenth fatality from electroshock treatment in the American literature, and the seventh with a necropsy report. The cellular changes found were mainly the result of the presence of a tumor. What part of these changes resulted from the electroshock itself cannot be answered The case illustrates that when the brain is in a state of delicate balance it requires little electrotherapy to destroy it completely. While usually the changes produced seem to be physiologic and reversible, they may, in the presence of preexisting structural damage, eventuate in further permanent alterations When antecedent damage is not known to have been present, any resulting structural pathologic condition may be due to individual susceptibility. The evidence for such a supposition in human beings is not complete.

Distribution and Fate of Penicillin in Body.—Cutting and his associates compared the concentration of penicillin in the blood and in various tissues in rats and rabbits one half hour after the subcutaneous and intravenous injection of 1,000 to 10,000 units of penicillin. In both rats and rabbits the brain contained only a negligible amount of penicillin, and the liver, heart and striated muscle contained amounts approaching that in the blood. The penicillin content of the kidney is more variable than that of other organs. In the case of the rabbit the variability is less than in the rat, and the content, apparently, is significantly higher. Rabbit kidney contained almost fifty times the amount in the blood, while in only 1 instance was a concentration of this order found in rat kidney. Since penicillin is rapidly excreted in the bile, comparisons of blood and biliary concentrations were made after the intravenous injection of penicillin in dogs. Simultaneous measurements were made in saliva collected after cannulation of the submaxillary duct and augmented by electrical stimulation of the chorda tympani or the sympathetic nerve supply and injection of pilocarpine. It appears that the amount of penicillin which is lost in the saliva is negligible, while that in the bile may be somewhat greater. However, the amount lost in the bile would also appear to be without clinical importance. Biliary obstruction in rabbits did not influence the rate of disappearance of penicillin from the blood, but renal obstruction greatly prolonged its effect. Penicillin is not rapidly destroyed in shed blood at body temperature and even less rapidly in urine or isotonic solution of sodium chloride. Accordingly, the major portion of any administered penicillin is lost in the urine, with a minor part in bile and saliva, and the fate of the portion unaccounted for remains unknown.

Chronic Toxicity of Quinacrine.—Fitzhugh and his associates studied the lifetime effects of quinacrine on laboratory animals. Studies were made on a total of 180 albino rats. Five groups were placed on a high protein diet and five groups on a low protein diet. One group on each diet was given 100 parts per million of quinacrine, a second group 200, a third 400 and a fourth 800; a fifth, which was used as control, received the diet without the added quinacrine. At the 100 parts per million level the toxic effects of quinacrine were slight. At higher levels they became progressively more severe. At a level of 800 parts per million the rats showed most of the following changes: generalized yellow discoloration; high grade necrosis of the liver; regenerative changes in the remaining viable liver; upper abdominal adhesions; focal necrosis and/or fibrosis of the myocardium and voluntary muscles; basophilic granules in hepatic, renal and other cells; foamy macrophages in several locations; slight hyperplasia of the splenic pulp and bone marrow, and a low grade pulmonary consolidation. At a dosage level of 800 parts per million a high level of protein in the diet considerably delayed and reduced the severity of liver damage as compared to that seen with a low level of protein; at 400 parts per million this delay and reduction was only slight, and at lower levels it was not apparent. At 400 parts per million and lower levels of quinacrine, myocardial fibrosis and other cardiac changes became a factor equal to or greater than liver damage in causing the death of the animal. After eighteen to twenty-four months of feeding, rats on 200 parts per million of quinacrine in either a low or high protein diet frequently showed anatomic lesions as a result of the medication. Even at 100 parts per million there was a small amount of damage. The percentage of rats in which quinacrine caused cirrhosis of the liver was so small that quinacrine cannot be classed as a distinctly cirrhogenic agent. In relation to the body weight of the rat the lowest dosage of quinacrine which produced slight toxic effects in some animals corresponds to approximately 4 mg. per kilogram a day for two years. The authors found that the amount of quinacrine that will produce toxic effects in rats is above the therapeutic or prophylactic dose for man.

Sulfonamides for Bacillary Dysentery.—White and his associates found that sulfacarboxythiazole (2-sulfanilamido-5-carboxythiazole) was about as active as sulfaguanidine against twelve dysentery strains in vitro and against coliform bacteria in mice. With respect to solubility, absorption and mode of action, sulfacarboxythiazole appeared to be similar to sulfathalidine (N^4-phthalylsulfathiazole). Sulfamethylcarboxythiazole (2-sulfanilamido-4-methyl-5-carboxythiazole) decarboxylates quite readily to sulfamethylthiazole. Consequently, further investigation of this compound as a possible chemotherapeutic agent does not appear to be warranted. 2-Sulfanilamido-4-carboxythiazole does not decarboxylate readily but is relatively inactive. Sulfathiadiazole (2-sulfanilamido-1, 3, 4-thiadiazole), when compared with sulfaguanidine, was found to be about ten times as soluble at p_H 6.5, from four to eight times as active against dysentery strains in vitro and more active against coliform bacteria in mice. These properties, together with preliminary data on its absorption in mice, indicated that sulfathiadiazole is at present one of the most promising compounds available for trial in the treatment and prophylaxis of bacillary dysentery.

Osteitis Pubis Following Prostatectomy.—Muschat says that osteitis pubis occurs in a small number of patients after operations on the urinary bladder, especially after prostatectomy. It is an inflammatory process of the bone beginning in the symphysis pubis and gradually involving the pubic rami extending to one or both ischia. This inflammatory process spreads via the periosteum to the variously attached muscles of the pelvis, especially the obturator. The etiology of this condition is obscure. The patient goes through a period of physical agony lasting from three to twelve months. The disease begins about ten days after operation but may not begin until two months later. The pain usually starts over the symphysis, gradually shifting to the right or left of the suprapubic area. Next the pain travels to the crotch, to the triangle of Scarpa and to the inner side of the thighs. Later in the disease there may be pain in the perineum and over the tuberosities of the ischia. The patient experiences excruciating pain in the inner side of the thighs in the form of spasmodic contractions of the adductor muscles. About the third week the x-ray begins to reveal some changes in the symphysis pubis, namely fraying of the periosteum with a moth eaten appearance of the symphysis and the ramus pubis on either side. As time progresses, more bone involvement is seen. Decalcification involves the rami and the inner portions of the ischia until the tuberosities are reached. Necropsies and complete study of the pathology of the bone structures have not been made. Most therapeutic agents that have been tried have been useless. In the author's opinion the disease is self limited and does not require surgical intervention. If an abscess does develop it should be properly drained. The author used penicillin 4,000,000 units in 1 case without any subjective improvement, but it may have caused the absorption of the inflammatory lumps near the ischia. Sulfonamides were tried without influencing the condition. Any manipulative procedure to hasten the recovery is strongly contraindicated. It only aggravates the condition and stirs up local trauma, thus spreading the disease process and delaying the recovery.

New Therapy in Headache of Essential Hypertension.—On the premise that recumbency seems to favor production of the cephalalgia, Steiner instructed patients to elevate the headposts of their bed on 10 inch high blocks. Of 12 patients in whom elevation of the head of the bed during sleep was employed, 10 obtained dramatic relief of their complaint. Four patients required oral ergotamine therapy and obtained complete relief after a week's course of medication. In only 1 case was there partial failure. This patient was unable to sleep with more than 5 inch elevation of the head of her bed. Nicotinic acid was prescribed in several cases on the hypothesis that this headache, like migraine, is of a primary vasoconstrictor type. It was without value. Phenobarbital and thiocyanates were used prior to institution of the present therapy. They also were ineffective.

Fibrin Fixation Methods of Skin Grafting.—Fibrin fixation methods of skin grafting by the technics of Tiderick and Warner and of Sano were tested by McEvitt in a number of typical situations such as grafting of a raw area over the anterior surface of the chest resulting from radical mastectomy, grafting for burns involving the left axilla and the lateral chest wall in a boy 5 years old, grafting of the forehead, of the eyelids, of the cheek and buccal margins and of the dorsum of the hand for third degree burns and grafting for third degree burns on the left lower extremity from the groin to the ankle. Both technics produced fixation of all types of grafts on both raw and granulating surfaces in a matter of seconds. The grafts remained healthy and viable. "Thrombin topical," a sterile powder prepared from beef plasma and used in Tiderick and Warner's technic, has the advantage of being produced commercially in quantity and delivered by the manufacturer ready for use. The elimination of pressure dressings promotes comfort and earlier movement of the part. Tissue maceration does not occur, and the bedside care of children is simplified. In certain areas of strain such as the interdigital webs and about the mouth, fibrin fixation without pressure dressing involves the risk of graft separation and slough. In such danger areas the combination of fibrin fixation and pressure should improve results. While the elimination of suturing does avoid troublesome bleeding, the advantage is more than counterbalanced by the difficulties inherent in graft shrinkage. In situations where grafting must be done in the presence of infection, fibrin fixation would seem to be the method of choice. It is a definite aid in adhering flap linings. Fibrin fixation methods properly applied are a valuable addition to the armamentarium of the plastic surgeon.

Scurvy.—From 1937 through 1944 Osterlin observed 68 cases of scurvy, 24 of these at the Central Michigan Children's Clinic during 1943 and 1944. More cases have been seen during the past two years than during any of the preceding years. The disease occurred predominantly (58 cases) during the latter half of the first year of life, when the baby is likely to be on a milk formula without getting sufficient vitamin C from supplementary foods. Irritability, pain on motion, poor appetite, vomiting, diarrhea and sore mouth were the most common symptoms found in this group. Scorbutic rosary, tenderness, particularly in the lower extremities, malnutrition, swollen and bleeding gums, pallor and petechia or purpura were the most common physical findings. Studies showed some or all the typical x-ray findings of vitamin C deficiency. Some form of vitamin C should be given every infant beginning with the first month, particularly those fed on an artificial formula. There are many infants who refuse to take or who vomit orange juice when attempts are made to give it. Fifty mg. of ascorbic acid can easily be given daily. An educational program on the part of physicians and public health workers is essential for the control of scurvy.

Procaine Infiltration in Acute Sprains.—Through a skin wheal using a long intramuscular needle all tender areas about the ankle joint are thoroughly infiltrated with 20 cc. of a 1 per cent procaine solution without epinephrine at each site. It has not been necessary to introduce the procaine into any hematoma which may be present, a general diffusion of the involved area being entirely satisfactory. On completion of the injections the ankle is gently massaged, and manipulation of the joint is undertaken. The foot is carried into all positions, and if discomfort persists the injection is repeated. With satisfactory injection there is immediate relief of pain. Excellent results were observed following primary procaine infiltration in nine tenths of the 51 cases seen within twenty-four hours after the injury occurred. The principal factors which may prevent this method from being successful are delayed injection, inadequate injection and extensive ligamentous damage.

Camptocormia.—Weiss reports 3 instances of camptocormia after spinal puncture in prisoners in a disciplinary center. Camptocormia is a symbol. When it develops in combat or combat training it is explained by "Duck when you're in danger." Suggestion on the part of the physician is a potent etiologic factor in camptocormia. The disability may be brought about unintentionally by the concern and ministrations of the doctor who seeks and treats an organ reaction without recognizing the emotional-functional basis of the condition Prolonged examination is neither necessary nor desirable lest excessive concern and ministration lead the patient to believe his condition serious Like other forms of hysteria, camptocormia can be made to disappear in the same way it develops —through suggestion The author puts special emphasis on intravenous barbiturate narcopsychotherapy

Sympathectomy in Immersion Foot and Frostbite—Many first degree cases heal without residual disability in about six weeks Approximately 25 per cent of such patients have bothersome complaints of a neuritic or vasospastic nature Many of the second degree injuries heal as do the first degree type as far as the acute manifestations are concerned Approximately 75 per cent of these patients have complaints of a neuritic or vasospastic nature In third degree lesions amputations are obligatory and neurologic and vasospastic complications are absent The late manifestations of immersion foot or frostbite fall into three groups disturbances of cutaneous sensation, inadequate circulation and pain on use In first and second degree cases the changes may not become static until eighteen months after injury Southworth does not employ sympathetic block or ganglionectomy in acute stages of immersion foot For the treatment of certain sequelae of frostbite or immersion foot, however, sympathetic nerve block or ganglionectomy appears to be indicated The disturbances of cutaneous sensitivity are almost invariably removed by sympathectomy In some patients a temporary sympathetic block not involving the somatic nerves immediately restores cutaneous sensitivity and relieves hyperesthesia In others there is a return to normal within two or three days after ganglion block by alcohol injection or ganglionectomy, but it should be noted that these symptoms do not usually contribute much to permanent disability If persistent and annoying symptoms of circulatory insufficiency resembling vasospasm are present, sympathectomy is helpful If excessive sweating, Raynaud's phenomenon or intermittent claudication is prominent in the clinical picture, sympathectomy results in great improvement Since these symptoms tend to regress spontaneously, the decision to perform sympathectomy may be safely postponed If thinning of the skin appears within the first three months, sympathectomy should be performed Otherwise alcohol block may be used for symptomatic relief Deep seated pain, which is often the principal disabling symptom, does not respond to sympathectomy Sympathetic denervation produces beneficial effects on certain late symptoms but does not always prevent partial disability

Penicillin in Tetanus.—Weinstein and Wesselhoeft report 2 cases of tetanus in which recovery followed treatment with large amounts of antitoxin, surgical excision of the wounds and administration of large doses of penicillin Clostridium tetani could no longer be isolated from the wounds twenty-four hours after the first administration of penicillin The already demonstrated antibiotic influence of penicillin on this organism in vitro appears to be confirmed in vivo The use of penicillin in tetanus appears to be most valuable in cases in which multiple lesions not all of which can be removed by surgical means are present or in which no focus of infection is detectable This antibiotic agent is not intended to replace the administration of antitoxin, excision of wounds, adequate sedation and maintenance of a normal state of nutrition and hydration but appears to be a highly important adjuvant to these other therapeutic measures

Penicillin for Vincent's Ulcers of Tonsils.—Joseph selected patients for this series who had necrotic, ragged tonsillar lesions of the type commonly known as Vincent's ulcers. Patients with gingival lesions as the primary complaint were referred to the dental clinic for their entire treatment. The first 6 patients were hospitalized and given four 25,000 unit doses of penicillin intramuscularly at three hour intervals. All patients experienced symptomatic relief in from six to nine hours, and the lesion cleared up entirely in seven days. With these favorable results hospitalization was discontinued for subsequent cases, and efforts were directed toward simplifying the regimen. All patients henceforth were kept on full duty. During the first two months the mode of administration and size of dosage were varied in order to arrive at the most practical method and smallest effective dose. Ten patients received 50,000 units, 13 received 25,000 units and 3 received 12,500 units. Some of the 25,000 and all of the 12,500 unit injections were made directly into the tonsil capsule to determine whether this would increase the efficacy of the drug. Two patients were treated with penicillin by topical application. Five others were given the drug orally in cottonseed oil in doses of 50,000 units each before the next two meals when the stomach was empty. It was found that 100,000 units of penicillin in two 50,000 unit intramuscular doses three hours apart provide optimal treatment for Vincent's ulcers of the tonsil.

Folic Acid in Macrocytic Anemia.—Vilter and his associates administered synthetic folic acid (Lactobacillus casei factor) to 14 patients with macrocytic anemia in relapse. The group included both addisonian pernicious anemia and nutritional macrocytic anemia. The material was given intravenously, intramuscularly and orally. Thirteen of the 14 patients showed a positive hematologic response consisting of reticulocytosis and subsequent rise in erythrocytes, hemoglobin and leukocytes. Where treatment was continued, the regeneration continued to normal levels. Erythrogenesis occurred regardless of the route of administration of folic acid and regardless of the clinical classification as to pernicious anemia or nutritional macrocytic anemia. The responses to treatment paralleled those afforded by potent liver extract. Synthetic folic acid (L. casei factor) is a potent hemopoietic agent. It is probably no more effective than liver extract in the treatment of macrocytic anemia.

Unusual Glandular Manifestations of Mumps.—Schmidt reports the history of a boy aged 6 in whom epidemic parotitis was followed first by swelling of the submaxillary lymph nodes and later by femoral adenitis. Two other cases were seen during the same epidemic in which similar involvement of the femoral lymph nodes was noted without manifestations in the salivary glands. These cases not only demonstrate another manifestation of mumps but likewise substantiate the opinion that the infection is not to be considered a local disease with possible complications but rather a systemic disease capable of producing pathologic changes in many different and highly specialized tissues. The author cites reports which indicate that immunity is more a matter of immunity of previously involved glands than of a general or systemic condition. Frequently persons are encountered who have never contracted the disease even though repeatedly exposed. Considering the highly contagious character of the infection and the results obtained by Enders, it may be assumed that many patients have had the disease without salivary gland manifestations.

Surgical Treatment of Deep Phlebitis of Leg.—Buxton and Coller report observations on 24 patients with chronic phlebitis of the lower extremities. The largest numbers presented themselves because of chronic recurring ulceration around the ankle. Ligation of the left femoral vein was done most frequently. Two patients had bilateral vein ligations. The common iliac vein was ligated once. Seven patients with long standing phlebitis of both lower extremities underwent ligation of the inferior vena cava. Patients on whom vein ligation has been tried have been followed and observed during their postoperative period with much greater intensity and care than usual in this disease. This has undoubtedly influenced the end results. Had this not been done, the good results up to the present time might well have been no different than with other forms of treatment. How much the end results are influenced by the operative procedure and how much by the constant postoperative care cannot be stated. The noteworthy end result is the high incidence of healing of stasic ulcers. There has been immediate and permanent healing of a certain number of ulcers. In others healing has been delayed or ulceration has recurred and healing has taken place only after ligation of newly developed superficial varices. The results were most disappointing in those in whom ligation was done in the absence of stasic ulceration. A large number of this class of patients will eventually develop induration, pigmentation and ulceration, perhaps many years later. In these, venous ligation was considered an attempt not only at therapy but at prophylaxis. From the standpoint of therapy the treatment may be considered a failure. It remains to be seen whether subsequent ulceration has been prevented in these patients. A comparison between patients treated with femoral vein ligation, iliac vein ligation and caval ligation cannot be made at present. The magnitude of the operative procedure is considerably greater, the higher in the venous tree ligation is carried.

Venous Pressures in Disorders of Venous System of Lower Extremities.—Tyson and Goodlett usually took the venous pressure in one of the veins of the foot or ankle. The patient is placed in the supine position and the table adjusted so that a base line corresponding to the auricular level of the heart can be measured on the manometer. The largest caliber needle that can be introduced in the vein is used. The most satisfactory size is number 19. The authors use one of two methods. In one method the system of tubing is filled with isotonic solution of sodium chloride. The 3 or 4 inches of tubing to be attached to the needle is then filled with 2.5 per cent sodium citrate solution and the glass connector attached to the needle already in the vein. The solution in the glass tubing is slightly above the base line of the heart level. Blood is allowed to flow into the cannula and tubing, and the maximum elevation of solution in the glass tubing is read as the venous pressure. In the second method the system is filled with 2.5 per cent citrate solution and a three-way stopcock is used to connect the needle and the tubing. The citrate solution in the glass tubing is slightly above the expected venous pressure. The apparatus is then attached to the needle in the vein and the citrate solution allowed to run into the vein. When no further citrate solution runs into the vein, the pressure of the column of citrate then equals the venous pressure. The venous pressure in the lower part of the leg will rise when the femoral vein of the lower leg is occluded. A large number of pressure determinations were made. Venous pressure determination is important in the diagnosis of edema of the lower extremities. If the venous pressure is normal in the lower part of the legs after exercise it is fair to assume that the major venous channels of the lower part of the legs are patent and that the cause of the edema must be found elsewhere. Venous pressure determinations would appear to be valuable in following cases of venous thrombosis in the lower extremities during convalescence. It may be difficult to determine in which lower extremity a venous thrombus is present or whether the thrombus is present in both. Venous pressure determinations are useful in determining this point. Venous pressure determinations are more accurate than phlebograms to determine the patency of the venous system.

Removal of Foreign Bodies in Pericardium.—Watts and Toone report the histories of 2 soldiers, both aged 21, in whom foreign bodies were removed from the pericardial sac. Another case had been reported previously. At operation each of these patients showed extensive and dense adhesions between the epicardium and pericardium and around the foreign body which is thought to be responsible for the symptomatology and abnormal objective findings encountered. The patient's symptoms, the objective evidence of pericardial or myocardial changes and the possibility of future complications are to be balanced against the operative risk. Pain of a dull aching character in the low substernal and precordial areas, increased by exertion but without tendency to radiate to the neck or down the arms, was a common complaint of 2 of the patients. Following the surgical removal of the foreign body there was complete relief of pain. There was anxiety regarding the foreign body, and the men expressed a desire to have it removed, offered no objection to surgical intervention even though made well aware of the serious nature of the operation, and were most gratified after its successful completion. Surgical removal is advisable before the foreign body becomes encased in dense adhesions or fixed in an inaccessible area.

Sensitivity of Hemophilus Influenzae to Penicillin.—Gordon and Zinnemann examined 15 Hemophilus influenzae strains from the nasopharynx and 28 H. influenzae strains from bronchial secretions for penicillin sensitivity. The growths of 31 of these respiratory strains were completely inhibited by 2.5 units of penicillin per cubic centimeter of medium. Only 7 strains showed growths on mediums containing 5 units of penicillin per cubic centimeter, with evidence of considerable inhibition. The growths of 18 H. influenzae strains, 16 of which were of Pittman's type b and all of which were isolated from the cerebrospinal fluid, were completely inhibited on medium containing 5 units of penicillin per cubic centimeter. The growths of 16 strains were completely inhibited with 2.5 units of penicillin, the growths of 12 strains completely inhibited with 1 unit of penicillin, and only 3 strains completely inhibited with 0.5 unit of penicillin per cubic centimeter of medium. It is suggested that penicillin therapy is worthy of trial in cases of H. influenzae meningitis.

Sixth Nerve Paralysis After Spinal Analgesia.—Fairclough presents a theory which would account for the fact that the sixth cranial nerve often shows signs of injury after spinal analgesia earlier than any of the other cranial nerves and that it may do so even if its anatomic disadvantages do not exist. The varying stability of binocular vision makes it possible that any cerebral pathologic condition, even slight in degree, would cause a breakdown of the binocular system with resulting diplopia. Examination of these functions before and after spinal injection may prove of interest. Of the 10 patients studied 9 were examined after they considered that their eye condition had returned to *normal. Each of them had* some degree of esophoria and none had exophoria. The common symptoms following lumbar analgesia are headache, pain in the neck, dizziness, photophobia—the latter two symptoms may be due to threatening or partial diplopia—and diplopia. The 10 patients with paralysis of the sixth nerve appeared among 2,021 patients who had received spinal analgesia.

Observations on Keratoconjunctivitis: Cases Seen in Military Hospitals. R. J. Buxton.—p. 847.

Toxic Effects of DDT in Man.—Case states that DDT has been shown to be toxic to a variety of mammals. The main pathologic features are liver damage, loss of weight, anorexia, mild anemia, polymorphonuclear leukocytosis, and damage to the central nervous system. In the one case of human intoxication to be found in the literature, Wigglesworth reports heaviness and aching of the limbs, sleeplessness, "spasms of extreme nervous tension," prostration of such a degree as to confine the sufferer to bed for a fortnight, and involuntary muscular twitchings over the whole body on at least three occasions. Recovery had not taken place at the end of the year. The victim had been exposed to concentrations of DDT in acetone and in powder form far in excess of levels that might reasonably be met with in the routine use of the insecticide. The problem under investigation was the possible toxic effect of the use of a distemper containing 2 per cent by weight of the dry film of DDT in circumstances where the paint would be covered with a thin film of oil, the ambient temperature would be such that personnel at risk would be largely unclothed, their skin would be oily and sweaty, because of cramped accommodation large areas of oily skin would come into contact with the paint, and efficient washing of the body surface could take place only at relatively infrequent intervals. Two healthy male subjects were employed for this investigation. During the control period no measurable changes took place apart from a fall in p_H in the urine. After exposure to DDT distemper, there occurred diminution of reflexes, alteration in auditory acuity in both subjects, and patchy peripheral anesthesia in one subject. The production of a fine tremor in one subject is also probably significant. A great transitory fall of systolic pressure was observed in both subjects. The hematologic observations are of greatest importance, because they suggest that hematologic examinations, employing siderocyte levels, hemoglobin and red cell estimations, reticulocyte counts and leukocyte counts, and also urinary indoxyl sulfate estimations might all be useful tests in the prevention or early diagnosis of DDT intoxication. These experiments show DDT distemper to be toxic only under special conditions, possibly more severe than would obtain in practice, and do not form the basis for condemnation of the widespread use of DDT if proper precautions are taken. They do, however, emphasize that DDT intoxication in human beings is a hazard to be considered and guarded against.

Fatal DDT Poisoning in Child.—Hill and Robinson report the case of a child, aged 1 year and 7 months, who found a bottle of 5 per cent DDT in kerosene and drank about 1 ounce. Within ten minutes he began to cough and vomit violently, whereupon he was given palm oil. In a short while coughing and vomiting ceased, but his general condition worsened, and at about 12:30 p. m. he became comatose and had convulsions. Later the stomach was washed out and atropine was given, but the child died. Death was due to pulmonary edema, probably from paralysis of the respiratory center. The lethal dose was approximately 150 mg. per Kg. of body weight of commercially pure DDT—an amount somewhat less than that found for experimental animals. Two fatal cases of chronic DDT poisoning in dogs are described, with a histologic picture of centrolobular necrosis of liver and tubular degeneration of kidney with considerable calcification.

*Louse Borne Relapsing Fever Treated with Calcium Gold Keratinate. M. Wolman, M. Omar and M. Abu-Taleb.—p. 775.

Clinical Value of Muscle Biopsies.—According to Bowden and Gutmann muscle biopsy besides giving information about the state of the muscle fibers, is a form of nerve biopsy, because nerve fibers or empty Schwann tubes or motor end plates are almost always found among the muscle fibers. In a series of 140 biopsies from 86 cases only 7 did not contain such elements. The presence of empty Schwann tubes is evidence of a degenerative lesion of lower motor neurones, and the finding of normal fibers and empty tubes indicates a partial lesion. Indications for muscle biopsy: (1) To determine the state of muscles where atrophy is advanced, or where a vascular lesion is suspected. Surgical repair of nerves or long continued physical treatment is valueless if the muscles have been irreparably damaged. (2) To aid in the diagnosis of the type of lesion in the nerve and to determine whether satisfactory regeneration is taking place in partial or recovering lesions. (3) To differentiate between paralysis of myogenic origin and disease of the lower motor neurone. (4) There are special indications for the use of biopsies in certain cases of poliomyelitis: it is possible to decide whether the state of the muscle is such as to make further physical therapy valueless; biopsies from long-standing cases of poliomyelitis have suggested that axonal regeneration can take place. A piece of the affected muscle is removed under local or general anesthesia, the size varying with the type and size of the muscle; if possible the piece should be at least 1 cm. long by 0.5 cm. wide and thick. The specimen is placed at once on a strip of cardboard to prevent distortion and fixed immediately in 10 per cent formol saline. If the piece is sufficiently large, half is used for frozen sections and the remainder embedded in paraffin.

Calcium Gold Keratinate in Louse Borne Relapsing Fever.—Wolman and his associates treated alternate patients (80 of a total of 160) with louse borne relapsing fever by intravenous injection of 0.5 Gm. of neosolganal in 5 cc. of distilled water. Two other groups of 20 patients each were given the gold preparation. One was given 1 Gm. of neosolganal in 5 cc. of water and the other 1 Gm. in 5 cc. of a 10 per cent solution of calcium thiosulfate. Toxic reactions were watched for and observed in two fifths of the aforementioned group of 80 patients. The reactions were mild. There was no significant difference between the reactions in those who were given the drug in water or in calcium thiosulfate. Neosolganal does not constitute a hazard to the patient. The patients were free from spirochetes and apyrexial within a short time (usually twenty-four hours or less) of the injection. The incidence of relapses in the treated group was significantly reduced. Three patients in the experimental group and one in the control group died. This difference is considered to be due to chance.

Seven Cases of Cardiac Thrombosis Associated with Apparently Healthy Endocardium and with Acute Fatal Course. R. Letac.—p. 121.

Cardiac Myxedema and Hunger Disease.—Tourniaire reports a case of hunger disease characterized by emaciation, bradycardia, nocturia, edema of the legs, slight anemia and hypoproteinemia. Cardiac hypertrophy and a drop of the electric voltage in the absence of any sign of cardiac insufficiency suggested cardiac myxedema. The edema disappeared within one week as the result of rest and of the administration of liver extract and thiamine hydrochloride solution intramuscularly. The cardiac hypertrophy was not altered. The measurement of basal metabolism revealed a diminution of 35.8 per cent. Thyroid treatment was instituted. After twenty-three days of this treatment the heart shadow decreased considerably. The electrocardiogram demonstrated improvement. On the fifty-sixth day of the treatment the patient a metallurgic workman aged 56, gained 2 pounds (900 Gm.), the pulse rate was 80 and arterial tension was 150/90. Occurrence of myxedema in the course of hunger disease proves the part played by thyroid insufficiency in deficiency conditions and supports Van Bogaert's concept of alcoholic beriberi.

Spina Bifida Occulta with Atrophy of a Lower Extremity and Neurologic Crises. C. I. Urechia, L. Dragomir and T. Dragomir.—p. 340.

Protein Content of Cerebrospinal Fluid.—Kafka examined 500 cisternal fluids and found that the upper limit of the total protein content is 1.1 graduation marks in the cisternal fluid as compared to 1.3 graduation marks in the lumbar fluid. That would be approximately 26.4 mg. per hundred cubic centimeters for the cisternal fluid compared to 31.2 mg. per hundred cubic centimeters for the lumbar fluid, if the graduation mark of the special tube is accepted as equivalent to 24 mg. per hundred cubic centimeters. He designates his method of determination as "protein relation," because it is his aim to relate the individual values and compare them in different diseases. This method of protein relationship is suited for the determination of the upper limits of the total protein content. Various observations have indicated that for the determination of the protein relation it is essential not only to ascertain the centrifugation time and the number of revolutions but also to determine the protein content of a graduation mark. If this is done, great differences will not be detected between the results of the protein relation and the Kjeldahl determination. It is also pointed out that the different modifications of the Kjeldahl method involve certain sources of error. The author further mentions a serial method which is a simple control and directs attention to numerous minor manipulations that help to avoid errors.

*Results of Pulmonary Lavage in Bacteriologic Diagnosis of Tuberculosis. M. de Abreu.—p. 601.

Pulmonary Lavage in Diagnosis of Tuberculosis.—De Abreu performed pulmonary lavage on 80 patients with suspected pulmonary tuberculosis who either did not expectorate or whose sputum was negative for tubercle bacilli. One or 2 cc. of a 5 per cent tutocain solution was applied to the pillars of the fauces, the uvula and the pharynx. The lavage was performed five minutes later by introducing into the trachea by the supraglottic approach 20 to 40 cc. of isotonic solution of sodium chloride during inspiration. Cough and expulsion of contents from the lung were thus provoked. Tubercle bacilli were demonstrated in 19 out of 80 cases. Results were negative in fibrous and calcified pulmonary lesions and positive in the exudative or the fibrous exudative type, as well as in the presence of tuberculous cavitation.

*Cerebrospinal Fluid in Jaundice. R. González Bosch, E. D. Andia and Elvira Carri.—p. 1252.

Cerebrospinal Fluid in Jaundice.—González Bosch and his collaborators studied the cerebrospinal fluid of 15 patients with jaundice. The group included 2 patients with syphilis, 1 with neurosyphilis, 2 with cirrhosis of the liver, 3 with catarrhal jaundice, 6 with cancer of the liver, the bile ducts or the head of the pancreas and 1 with stone in the common bile duct. The changes of the cerebrospinal fluid in jaundice consisted in xanthochromia and the presence of bilirubin and bile salts. A relationship between the concentration of bilirubin in the blood and that in the cerebrospinal fluid was not present. The amount of sugar in the cerebrospinal fluid was normal even in cases in which the fluid contained bile salts.

*Weltmann's Serum Coagulation Reaction—A Simple Test of Considerable Clinical Value. R. Berlin.—p. 360.

Control of Paroxysmal Tachycardia with Acetylcholine.—Segers and his co-workers report 6 cases of paroxysmal tachycardia of extraventricular origin in which control of the crisis was obtained within less than thirty seconds of the time of intravenous injection of 0.02 Gm. of acetylcholine. In cases in which immediate control cannot be obtained, injections must be repeated at three to four minute intervals with increasing doses of 0.04, 0.06, 0.08 and 0.1 Gm. The dose may vary from 0.01 Gm. to 0.1 Gm., but in the same patient the required dose does not vary from one paroxysm to another. Mild secondary reactions were limited to attacks of coughing, nausea, a sensation of emptiness or of warmth in the head or a few palpitations. The absence of dangerous sequels to the injections is due to the very rapid destruction of the acetylcholine by the organism. Acetylcholine is much better tolerated than acetylmethylcholine chloride (mecholyl) or carbaminoylcholine chloride (doryl). The constancy of the favorable results, the mild and brief secondary reactions and the rapid control of the paroxysms suggest that acetylcholine is to be considered the agent of choice in the treatment of paroxysmal tachycardia.

Weltmann's Serum Coagulation Test.—Berlin reports experiences with the Weltmann test at the department for internal diseases of the district hospital in Lidköping, Sweden. A maximum shortened coagulation band was observed in pneumonia, exudative pleurisy, septic processes and nephrosis. Eleven of 14 cases of coronary infarction gave a shortened coagulation band on the fourth to the fifth day after the onset of the infarct, and the same reaction continued for a considerable time. The sedimentation reaction became normal much earlier. Three cases did not give a shortened coagulation band, but 1 case gave a shortened coagulation band a day earlier than the demonstration of the infarct by the electrocardiogram. A solution for the controversy with regard to the coagulation band in myeloma is suggested: Myeloma associated with nephrosis gives a shortened coagulation band, and myeloma without this complication gives a lengthened coagulation band. Weltmann's test is of great importance in pernicious anemia; 88 of 96 cases of various stages of remission, as well as of recurrence of pernicious anemia, gave coagulation band values around 7 or above 7. A shortened coagulation band suggests a malignant process. The Weltmann test aids in the differential diagnosis of jaundice. The author reports 53 cases of hepatocellular damage: 49 cases of hepatitis, 1 case of jaundice due to neoarsphenamine, 1 case of icterus intermittens juvenilis (Meulengracht) and 2 cases of yellow atrophy of the liver. Coagulation bands longer than 7½, according to Weltmann, are typical for these conditions. Only 10 of 53 cases (20 per cent) gave shorter values. Twenty-three of the author's 27 cases of obstructive jaundice on the contrary showed normal or shortened values of the coagulation band. In 4 cases of this group (15 per cent) the coagulation values were 7½ and 8 and thus were misleading.

Book Notices

Clinical Neurology. By Bernard J. Alpers, M.D., Sc.D., Professor of Neurology, Jefferson Medical College, Philadelphia. Cloth. Price, $8. Pp. 797, with 232 illustrations. Philadelphia: F. A. Davis Company, 1945.

Here is a new textbook of neurology which is well organized and thoroughgoing. It should receive a cordial reception. It will prove most useful to both students and practitioners. It is clearly written and well illustrated and has a good index. The typography is pleasing. The book has several valuable characteristics which differ from most other neurologic textbooks. Among these is the emphasis on symptomatology, on the clinical manifestations of nervous diseases and on differential diagnosis. There is one chapter, the fourth, devoted to a discussion of headache, vertigo, coma and pain. There are numerous tables enumerating signs and symptoms of various diseases and outlining the principal considerations in differential diagnosis.

In spite of these many favorable aspects of the book, and they greatly outnumber and outweigh the unfavorable ones, there is much room for improvement. There is much unnecessary and at times tedious repetition. This is constant in the text in little things. In a larger way, probably the most obvious example is the almost word for word repetition of the discussion of Sydenham's chorea on pages 383-385 and 620-623.

Some of the more specific criticisms which should be noted are the omission of the discussion of the surgical treatment of Ménière's syndrome on pages 124-126, the statement on page 200 that the pain of trigeminal neuralgia often arouses the patient from his sleep, the inclusion on page 201 of a discussion of jaw-winking reflex in the section on trigeminal neuralgia and the uncritical discussion of the treatment of tabes dorsalis on page 256. This lack of critical presentation of material collected from the literature is notable in several places and is serious in a book for students and general practitioners. On page 410 in table 39 there is reproduced a compilation of the contributory causes of cerebral hemorrhage which can hardly fail to give the student an erroneous impression. As the text indicates, arterial hypertension is by all odds the most common contributory cause of such hemorrhages and cerebral aneurysm is probably next. This is hardly a conclusion to be drawn from this table. On page 425 in table 41 similar misinformation is presented. In the table arteriosclerosis is a factor in only 54.7 per cent of the cases of cerebral thrombosis. In the immediately subjacent text it is stated that sclerosed cerebral vessels were found in 98.6 per cent of such cases. Similarly a tabulation on page 638 of precipitating factors in multiple sclerosis gives an inaccurate picture of the development of that disease. On page 697 the author correctly states that vitamin E is of little value in the treatment of amyotrophic lateral sclerosis and then proceeds to encourage the use of this worthless form of therapy by outlining in detail the method of administration. On page 752 the questionable clinical symptomatology of "benign frontal hyperostosis" is discussed at length and as though the direct relationship between the hyperostosis and the symptoms detailed was an accepted fact. In the discussion of extradural hemorrhage on pages 344-345 and of subdural hemorrhage on page 351, it is stated that such patients are "in shock," obviously with a most erroneous concept of what shock is. Patients are not in "profound shock" who have "a fall of the pulse, with a rise in blood pressure." Figure 110 would be more intelligible to most readers if it was inverted. The discussion on page 375 of mumps encephalitis and meningitis is confused and confusing.

However, this is a useful book, well organized and containing much valuable information.

The Hospital Purchasing File 1945-1946. Established 1919 as The Hospital Yearbook by The Modern Hospital Publishing Co., Inc. Directory of Hospital Products, Manufacturers' Catalogs, Reference Data. Twenty-third edition. Boards. Various pagination, with illustrations. Chicago: Purchasing Files, Inc., [n. d.].

This volume on hospital products and purchasing is a continuation of the Hospital Yearbook originally established in 1919. As in previous years, the book contains a vast amount of information including a directory of hospital equipment and supplies, an alphabetical list of manufacturers and distributors and twenty-two groups of manufacturer's catalogues classified on a departmental as well as a functional basis. The catalogues relate to administrative departments, food preparation and service, housekeeping, laundry, building construction, maintenance and repairs, plant operation, professional equipment and other facilities pertaining to surgery, obstetrics, hospital nurseries, anesthesia, physical and occupational therapy, and pharmacy, x-ray and laboratory departments. Featured also are special articles, references and plans for individual departments, check lists of hospital equipment and supplies, requirements for a 100 bed general hospital, and directories of the principal hospital associations and the federal and other national agencies serving the hospital and allied fields. The book is an excellent source of information and reference for hospital administrators and other personnel concerned with the services of supply, maintenance and hospital buying.

A Textbook of Surgery. By John Homans, M.D. Compiled from Lectures and Other Writings of Members of the Surgical Department of the Harvard Medical School. With a Special Bibliographical Index. Sixth edition. Cloth. Price, $8. Pp. 1,278, with 530 illustrations by Willard C. Shepard and others. Springfield, Ill., Charles C Thomas, 1945.

This excellent textbook of surgery is now in its sixth revision in fourteen years. This is indicative of the state of flux existing in the entire field of medicine. In surgery the recent accentuation of specialization makes the creation and revision of a general textbook on the subject increasingly difficult. This is reflected in the retention of outmoded concepts, a lag in correlation with recent advances in basic sciences and a reluctance to include newer treatments. The author has admirably overcome these objections in previous editions and has done considerably better in this one. It is pleasing to note the inclusion of lessons learned from the war, not as afterthoughts, but as dynamic factors in the modern surgical management. Fundamentally in outline and pagination there has been little change. The writing, as always, is clear and descriptive. Certain outmoded illustrations and descriptions have been eliminated to good advantage. A word about the excellent section on anesthesia by Dr. Knight should be included. It can be said without hesitation that this basic teaching contribution to the field of surgery has more than maintained its previous standards of usefulness.

Personality in Arterial Hypertension. By C. A. L. Binger, N. W. Ackerman, A. E. Cohn, H. A. Schroeder and J. M. Steele. Psychosomatic Medicine Monographs [Second Series, No. 8]. Cloth. Price, $3. Pp. 228. New York: American Society for Research in Psychosomatic Problems, 1945.

This monograph is a contribution to the field of psychosomatic medicine with 24 case histories and tables. The evidence, which is detailed, establishes conclusively the importance of psychologic causes for hypertension and explains many of the cases that would have been called in an earlier period essential hypertension. One of the patients in the series was investigated by psychoanalytic technics. The authors do not conclude that the disorder of personality is the cause of the hypertension; they conceive rather that the psychologic disorder and the physiologic disorder may represent reflections of a basic failure foreshadowed early in life.

Requirements of Premarital Legislation. By Margaret R. Zwally, M.A., and John F. Mahoney, M.D., Director, Venereal Disease Research Laboratory, United States Marine Hospital, Staten Island, N. Y. United States, Federal Security Agency, Public Health Service Bulletin No. 98. Paper. Price, 10 cents. Pp. 20. Washington, D. C.: Supt. of Doc., Government Printing Office, 1945.

The Venereal Disease Research Laboratory, U. S. Marine Hospital, Staten Island, New York, presents in this pamphlet a brief analysis of state laws requiring premarital physical examinations and blood tests as they relate to the venereal diseases. Information in summary form is given relative to the qualifications of physicians who may collect the required specimens or perform the required examinations, the laboratories approved for making the required tests and where the required forms may be obtained. Information is also given in tabular form concerning the type of examination required, the time needed to complete arrangements, appearance in person required to obtain license and source of information concerning waivers and so on. The material is current as of Jan. 1, 1945 and prior to publication was submitted for approval to the respective state health offices.

Red Surgeon. By George Borodin. Cloth. Price, $4.50; 15s. Pp. 224, with 19 illustrations. Forest Hills, N. Y.: Transatlantic Arts; London: Museum Press Limited, 1944.

George Borodin and Maxim Murov got to know and admire each other early in boyhood. The friendship was a clandestine one, for George was the son of a nobleman and Maxim the son of a revolutionary. When the revolution came, Borodin immigrated to England and in time became a prominent surgeon. Murov remained in Russia and in his turn soon came to occupy the position of one of the most gifted young surgeons and research workers. In the summer of 1942 the Germans were making their second great attempt to sweep everything before them. About this time Borodin received a bulky package which also contained a letter. It was from Murov: "I am writing in a little village in the southern sector. We have fought here for days and now the end must come. In front of us are Germans, behind us are Germans, to the left and to the right of us are Germans. Each hour brings the steel ring a little closer. There are not many of us left, and none of us will ever be prisoners. Some of us will die, as our comrades have died, not fearing death. Whichever is my fate, I am ready for it."

The second part consists of Murov's diary, translated and edited by the author. Two features of it should be of particular interest to the reader. One deals with the organization of the military medical service of the Soviet Union and the other with the man Murov. The principle of bringing fully equipped hospital units to the very front, and the principle of specialization, as practiced by the military organization in the Soviet Union, are well known here and are not unique with them. Of greater interest is the progress of a man from the cloister of the laboratory to the cauldron of the battlefield. One experiences in it first a shock and horror of war on a sensitive and discerning soul, and then the gradual acclimatization. Murov, primarily a scientist, a surgeon and a lover of humanity, slowly becomes a fighter and is the epitome of his people. The woman doctor Irina, a remarkable woman indeed, symbolizes the modern Soviet woman, seeing no reason why the burdens that men bear should not also be borne by women. She died a soldier's death. The book is an interesting psychologic study of a fine character symbolic of his profession.

Men Without Guns. By DeWitt Mackenzie, War Analyst of The Associated Press. Descriptive Captions by Major Clarence Worden, Medical Department of the United States Army. Foreword by Major General Norman T. Kirk, Surgeon General of the United States Army. Cloth. Price, $5. Pp. 47, illustrated with 137 plates from the Abbott collection of paintings owned by the United States Government. Philadelphia & Toronto: Blakiston Company, 1945.

Twelve of the artists who traveled with the medical corps of the Army and the Navy during the war and who showed in paintings made in the scene of battle the doctors, the nurses and the men of the medical corps in action are represented in this magnificent album of paintings of doctors at war. Of the plates, 118 are in full color. The project was approved by Surgeon General Kirk and sponsored by the Abbott Laboratories, which paid for the making of the paintings and then donated them to the United States government. Accompanying the pictures is a brief text which includes some account by the artists of their own experiences. The areas covered include the campaigns in the South Pacific and in Italy, Normandy and Germany. The paintings bring to life many an action that seems in photography without human sentiment. These paintings have power to stir emotion beyond anything that comes from a photograph. To the 60,000 physicians who served in the war they will be an enduring reminder of experiences that are epochal even in the lives of men to whom crises come every day.

A Handbook for Dissectors. By J. C. Boileau Grant, Professor of Anatomy, University of Toronto, Toronto, and H. A. Cates, Associate Professor of Anatomy, University of Toronto. Second edition. Fabrikoid. Price, $2.50. Pp. 390, with 10 illustrations. Baltimore: William Wood & Company, 1945.

This small book was originally intended to be used in conjunction with "A Method of Anatomy" for the purpose of supplying additional directions to dissectors. The present edition has been thoroughly revised and does not contain page and figure references to the larger book. This accomplishes two things. First, it is now possible for the present edition of the handbook to gain recognition in its own right. Second, the handbook may now be used as a guide for dissectors in schools where the "Method of Anatomy" has not been adopted as a textbook. Enough information has been supplied for the proper orientation of the beginner. The more fundamental structures have been indicated by a systematic discrimination in the use of bold type. The directions are clear and concise. This book should be of great value to students who are not furnished with directions for dissection by their own teacher.

Using Standards and Labels: A Problem of the Modern American Consumer. A Unit for High School Students. Consumer Education Series Unit No. 6. Paper. Price, 25 cents. Pp. 128, with illustrations. Washington, D. C.: Consumer Education Study, National Association of Secondary-School Principals, A Department of the National Education Association, 1945.

Publications of the Consumer Education Study of the National Association of Secondary-School Principals of the National Education Association are intended to promote consumer education, which is undergoing rapid development in secondary schools. Because the content of courses varies with the school, those responsible for this series of teaching-learning units have concentrated on general principles underlying consumption and have not concentrated on the skilled purchasing of specific commodities. The units are intended to help young people to become more intelligent and conscientious consumers. The Consumer Education Study, which is financed by funds from the National Better Business Bureau, has prepared in this unit an interesting survey worthy of reading by the general population; its use should not be confined to secondary schools. It is accurate, informative and provocative; it will force the reader to appreciate the need of scientifically developed standards and the value of purchasing products which meet these standards.

The Person in the Body: An Introduction to Psychosomatic Medicine. By Leland E. Hinsie, M.D., Professor of Psychiatry, College of Physicians and Surgeons, Columbia University. New York. Cloth. Price, $2.75. Pp. 263. New York: W. W. Norton & Company, Inc., 1945.

Here for the average American physician is a good consideration of the fundamentals of psychosomatic medicine. The book is well written, the cases are well selected and the material is definitely pointed toward the general practitioner. One of the most valuable chapters is the one headed "Varieties of Psychosomatic Syndromes." Other important chapters are called "The Body Protects the Person in It" and "Types of Neurotic Personalities." A final chapter entitled "Your Part in Psychotherapy" is directed particularly to the patient who requires psychosomatic medicine.

The Yearbook of Psychoanalysis. Volume I. Managing Editor, Sandor Lorand, M.D. Cloth. Price, $10. Pp. 370. New York: International University Press, 1945.

Under the editorship of Dr. Lorand there are here collected from a variety of publications in the field of psychoanalysis a number of important essays. The present volume covers the years 1942 through 1944. Future volumes are to be concerned only with current contributions of the previous year. Many of the leading American authorities in the field of psychoanalysis and psychosomatic medicine contribute, and several of the essays are concerned largely with war.

A List of Books and Pamphlets on the History of Surgery and Orthopedic Surgery, with Supplement, Additions and Corrections. The Collection of Dr. H. Winnett Orr, M.D. Second edition. Cloth. Pp. 207, with illustrations. Lincoln, Nebraska: The Author, 1945.

This volume is essentially a catalogue of works on the history of surgery and orthopedic surgery in the library of Dr. H. Winnett Orr. It includes as well many books somewhat remote from that field. A striking feature of the catalogue is the reproduction of title pages of many of the earlier publications.

A Surgeon Looks at Life. By Richard A. Leonardo, M.D., Ch.M., F.I.C.S. Cloth. Price, $2. Pp. 128. New York: Froben Press, 1945.

Dr. Leonardo presents fifteen chapters which represent fifteen philosophical essays on the subjects discussed. They range from considerations of faith cures and euthanasia to life after death and building a good life.

Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

RELAPSE WITH VIVAX MALARIA

To the Editor:—I am a medical officer of the Army of the United States and served overseas nineteen months in the Southwest Pacific area. While overseas we all took atabrine regularly to suppress symptoms of malaria. When I left the theater it was recommended that atabrine be continued for a period of twenty-eight days after arriving in the United States. I continued taking atabrine for forty-five days after my arrival and discontinued taking it Oct. 15, 1945. On November 6 I developed chills and high fever and was admitted to the hospital with the diagnosis malaria tertian, new. I shall be discharged within the next few weeks and have contemplated settling in Texas or some other Southern state. Are there any data as to the recurrences of malaria, disregarding new infections, with relationship to climatic conditions? Would it be more advisable to settle in a Northern state rather than in a Southern state? Major, M. C., A. U. S.

Answer.—The history of relapsing with vivax malaria two months after leaving the endemic area is common. As a matter of fact, 1.7 per cent of 2,579 patients at the Marine Barracks, Klamath Falls, Ore., had their initial attack over one year after leaving the endemic area. The use of atabrine after all chances of being reinfected are no longer possible only insures freedom of clinical symptoms as long as taken. It does not cure.

There is no conclusive evidence that recurrences of malaria are any more frequent or persistent in the Southern than in the Northern states, if reinfection possibilities are excluded, although there is some indication that altitude is beneficial, as it stimulates the hemopoietic system. Data to date indicate that Southwest Pacific malaria is self limited but unusually persistent. There is some evidence that rational therapy should consist in the treatment of relapses as they occur rather than continuous suppressive medication.

HYPERPIGMENTATION OF UNCERTAIN ORIGIN

To the Editor:—A woman aged 50 has been taking diphenylhydantoin (dilantin) sodium 0.1 Gm., capsules twice daily for thirty-two months with good control of epileptic seizures. She has been using Roux for many years as a hair dye. She is naturally of dark complexion and claims that her skin in the exposed area, i. e. above the clavicle and extending up into the cervical region, is becoming more deeply pigmented. There does seem to be an increased area of pigmentation in this region. Physical examination is negative. I myself do not feel that there is a pathologic pigmentation but that the patient has an antipathy toward diphenylhydantoin and seeks an excuse to discontinue it. Could either diphenylhydantoin sodium or Roux cause a disturbance of pigmentation? M.D., New York.

Answer.—A rapid survey of the literature does not reveal reports of increased pigmentation following the use of diphenylhydantoin sodium. Hyperpigmentation from the dye would probably follow an inflammation from an induced dermatitis venenata or contact dermatitis. If so, the dermatitis and postinflammatory pigmentation should have been present near the hair line and on adjacent parts besides those described as actually involved. Other causes for a dermatitis venenata too mild to be conspicuous may be present. Finger nail polish commonly affects the region of the eyelids, but the neck too is frequently an affected site. Chloasma may produce such hyperpigmentation. The color is brownish, unless the degree is intense. Then the hue is more blackish. The discoloration in this disorder is more apt to occur in poorly defined patches on the face. It accompanies usually, but not always, either pregnancy or inflammation in the pelvis. When neither one of the latter is present, the cause is difficult to find. So-called berlocq dermatitis may be the cause of the hyperpigmentation described in the query. This type of reaction occurs in some persons who become sensitized to ultraviolet rays after the use of essential oils, such as are present in cologne or perfumes. The sites at which these are applied are the ones which become hyperpigmented. A preliminary dermatitis may not precede the increased pigmentation or may be so mild as to escape attention. A condition called Riehl's melanosis may occur on exposed parts and was described as a war melanosis. Another disease probably the same as the war melanosis or similar to it is the poikiloderma of Civatte. In this the hyperpigmentation occurs on the sides of the neck and face. The discoloration is reticulated, or netlike. A more accurate description of the form and color of the increased pigmentation would be helpful in order to evaluate better some of the many possible causes of this discoloration.

CRACKS AND FISSURES OF THE NASAL VESTIBULE

To the Editor:—I have had several patients with a small crack inside the top of the nose. In at least 1 case a dermatologist was consulted. I have not had success in treating these cracks, which are extremely chronic or recurrent. Can you tell me anything of the etiology and treatment? F. L. R. Roberts, M.D., Spirit Lake, Iowa.

Answer.—The cracks or fissures described are to be considered as a form of dermatitis of the nasal vestibule and are accompanied by pain, redness, excoriation and crusting. The interior of the nose should be searched for the presence of undue secretion such as is seen in purulent sinusitis and allergic states. It is these states that are thought to be the underlying causes of the vestibulitis.

The treatment of the fissures themselves consists in applying silver nitrate solutions in varying strengths (5 to 20 per cent) and then following with applications of a mild ammoniated mercury ointment (2.5 to 5 per cent). Instead of silver nitrate, some advocate the use of stronger caustics such as trichloroacetic acid (50 to 90 per cent). Lastly the actual cautery may be tried in the more stubborn instances in which granulations have arisen on the borders of the fissures. The underlying sinusitis or allergic state also should receive attention.

PRECOCIOUS PUBERTY

To the Editor:—Please send information on treatment for halting premature puberty. The girl is 5 years old with fairly well developed signs of puberty, pubic hair ½ to ¾ inch long, pointed breasts and shaped hips and legs. She has been having abdominal cramps at regular intervals for six months; no menses have been noted as yet. The father is normal. The mother menstruated at the age of 11. The mother had to take thyroid and pituitary during pregnancy. M.D., New York.

Answer.—Isosexual premature or precocious puberty in girls is usually the result of an ovarian tumor of the granulosa or theca cells or due to a constitutional condition in which there are no demonstrable organic changes. Usually the precocity from an ovarian tumor occurs about the ages 8 to 10, and rarely at the age of 5. If such a tumor can be ruled out through pelvic examination, diagnosis would then be constitutional premature puberty. Up to recent years no treatment for this condition has been recommended. However, it would seem quite likely that the administration of androgens such as testosterone propionate would be useful in controlling the abdominal cramps recurring each month as well as delaying other signs and symptoms of puberty. Such treatment should be attempted cautiously, since relatively little is known regarding the dosages of androgens in girls at this early age. It is suggested that 10 mg. of testosterone propionate might be administered at weekly intervals and increased slowly if there are no changes in the ovarian cycle. If this dosage is successful, the patient may be maintained on methyl testosterone orally, about 5 mg. daily. After several months of therapy a rest period should be instituted and treatment resumed on return of symptoms. Overdosage can be recognized by the appearance of acne, lowered voice and hirsutism, and treatment stopped if these appear. It can be started later at a lower level if necessary.

CARE OF BED PANS

To the Editor:—I would appreciate it if you will let me know whether there is any procedure or recognized system of washing or sterilizing bed pans each time they are used and after the patient leaves the hospital when that bed pan will be used by another patient. Oscar Gottfried, New York.

Answer.—In one large teaching hospital, bed pans are kept in a rack in the lavatory connected with the room where the patient is in a private room and cleaned as indicated. They are sterilized after the patient leaves the hospital. In the wards, bed pans are in a utility room. After use, the pan is cleaned, sterilized and replaced on the rack.

TUBERCLE BACILLI H 37RV

To the Editor:—Please tell me what is meant in tuberculosis study by strain H 37RV. H. H. Schultz, M.D., Ingleside, Neb.

Answer.—By H 37RV is meant a strain of tubercle bacilli of human type disassociated from the well known Saranac H 37 strain by William Steenken Jr., which grows in the form of rough colonies and has the virulence characteristic of a human type tubercle bacillus.

COLOSTRUM PREGNANCY TEST

To the Editor:—Can you give me an opinion concerning the reliability of the Falls-Freda technic for the skin test diagnosis of pregnancy as manufactured and distributed by the Sherman Laboratories of Detroit?

Paul J. Bronson, M.D., Terre Haute, Ind.

Answer.—According to the claims made for the Falls-Freda pregnancy test a diagnosis of pregnancy can be made following the intracutaneous injection of an extract of colostrum, a wheal indicating pregnancy, and its absence a negative test (Falls, F. H.; Freda, V. C., and Cohn, H. H.: *Am. J. Obst. & Gynec.* **41**:431 [March] 1941). These claims have not been confirmed by a number of investigators, including Weisman and Snyder (*ibid.* **42**:738 [Oct.] 1941). In spite of this lack of confirmation the advertising has induced many physicians to purchase the test for clinical use. No other skin tests for pregnancy have proved reliable in which either extracts of placenta or the urine of pregnant women is used. The biologic tests for pregnancy involving the use of rats, mice and rabbits are still the most practical and reliable.

FACIAL TIC

To the Editor:—A white man aged 43, a druggist, has had a facial tic for the past ten years in one side of the face involving the eye, the muscles of the face, the platysma and the occipital muscles. This tic is both clonic and tetanic in character, and the spasm occurs every ten minutes and lasts about three minutes. The spasm starts with clonic contractions and gradually goes into the tetanic type, shutting the eye completely for a minute. The patient has no pain with this tic. He is intelligent and has no neurotic background. The eyes, ears and nose are essentially normal. He was treated for frontal sinusitis on several occasions. A nose and throat physician took an x-ray of the sinuses eight years ago and the report read "left sphenoid and posterior ethmoiditis; polyp, moderate size, in right antrum." He is in good health. A Hinton test is negative for syphilis. A neurologist was consulted, and he advised cutting the facial nerve, using the spinal accessory nerve to get impulses through the peripheral fibers and suspending the face with fascia so that the loss of the facial nerve would be completely disguised. The patient refused to have the facial nerve cut. What is the latest procedure in treating such a tic? Will a nerve crushing or stretching help? How about alcohol injections? Will any medicine alleviate, at least temporarily, facial tics? Should neostigmine be tried in this case?

M.D., Massachusetts.

Answer.—This is the description of a typical and severe hemifacial spasm. The cause of the condition is not clear, but it seems most likely that it results from some irritation of the facial nucleus in the brain stem. In the milder cases sedatives may prove of some benefit, but in the main medical treatment in all forms has been disappointing. Any procedure which interrupts the function of the facial nerve such as cutting the nerve, crushing it or injecting alcohol will stop the spasm. However, all of these cases entail a facial paralysis of varying degrees of permanence involving sections of the facial nerve, and anastomosis with the spinal accessory nerve would seem to be the procedure of choice. But as the patient refuses to have the nerve cut all of these operations would seem to be excluded. In any event none should be undertaken until after the nerve has been temporarily paralyzed with procaine so that the patient may be fully aware of the nature of the facial paralysis.

GOGGLES FOR UNDERWATER SWIMMING

To the Editor:—I am anxious to get a treatment for a pair of special lenses for eye glasses. This idea is that I enjoy under water swimming and would take even more pleasure in it if it was possible for the normal human eye to focus when a watery medium is in contact with the cornea. Unfortunately, it can't be done; and furthermore the ophthalmologists whom I happened to consult couldn't compute a treatment for the lenses. I have no visual defect and so the only consideration would be what convexity needs to be put up to accommodate for the diminished refraction when the eyes are immersed. Perhaps the question How far in front of the corneas should the lenses be placed? needs to be answered. I am not interested in contact lenses if ordinary spectacles can do the job.

Glenn J. Potter, M.D., Los Angeles.

Answer.—There is no treatment that can be applied to lenses that would in any way change the refraction of the glass, which answers the first sentence of the inquiry. Contact lenses certainly would not alter the ability to see under water. The only possibility is that a pair of goggles could be used under water which are more or less of a protection against eye infections and irritation due to continual or long periods of swimming. Such a goggle may be obtained from Abercrombie and Fitch, which is in the form of a rubber goggle fitting snugly so as to eliminate water coming in contact with the eyes.

PAINS IN THIGHS WITH LYMPHADENOPATHY

To the Editor:—A white married woman aged 23 complains of severe aching and cramping pain in both thighs while at work. She is a beauty operator and has been working quite hard, and part of the time she may be standing quite still for some minutes, when the pain becomes worse. On examination there are no varicose veins and no obesity (weight 120 pounds, or 54 Kg.). There are several palpable tender lymph glands in the popliteal space and extending up the posterior side of the thigh. There is no lesion of the skin where infection might have gained entrance. There is a mild endocervicitis. The rest of the examination is essentially negative. I am unable to account for the pain. Can you suggest from these meager findings what might be the probable diagnosis or what other examination might reveal the diagnosis? M.D., Washington.

Answer.—Any explanation of the symptom on the basis of the facts stated encounters some objection. The tender lymph glands in the popliteal space must mean infection below this level unless there is generalized lymphadenopathy, which the correspondent has not reported. In any event the infection which would produce these glands must lie below the level of the thigh. The same objection must be raised against a possible circulatory obstruction. Any circulatory obstruction in the pelvis, where it must be to produce bilateral pain, would produce pain below the level of the thigh. Aching and cramping pain brought on by work is suggestive of a circulatory deficiency, and in spite of the lack of pain in the lower part of the leg it might be worth while to test the circulation by means of histamine flares or estimations of the skin temperature.

The other possibility that suggests itself is some involvement of the nerve supply. Again the bilateral distribution militates against such a possibility, but it is possible that a bilateral bony lesion such as an osteoarthritis (unusual in a patient of this age) might produce such symptoms. A lesion of the cauda equina or the conus medullaris must be considered, and a thorough neurologic examination is indicated.

Lastly the signs might be due to postural causes or to a congenital deformity of the lower lumbar spine. This also should be disclosed by x-ray examination.

TRAUMA AND HEART DISEASE

To the Editor:—A recent case in which I am interested, involved an award made by a workmen's compensation court to a petitioner who suffered a strain on the left side while operating a motor truck. In attempting to steer the vehicle he was driving around a sharp turn, it was necessary for him to brace one leg against the instrument panel board of the truck and then exert his strength to turn the vehicle. The man had suffered from a hydrocele for six years, and in visiting a doctor four hours after the incident his complaints were of pains radiating from the scrotum to the upper part of the abdomen. (Incidentally, he made the same turn three additional times within four hours.) Ten days after the occurrence he was operated on for repair of the hydrocele, and after three months' rest he resumed his employment as a truck driver but had to discontinue the work, owing to his physical condition becoming weakened. At the compensation trial, physicians testifying in his behalf stated that the man was really suffering from an endocarditis and in their opinions the strain aggravated a condition which would have remained quiescent. Their estimate of the disability due to trauma aggravating a preexisting condition was 50 per cent of total, which award was made by the compensation commissioner. Discussion of the case with fellow physicians convinces me that my opinion was correct in that there could not have been an aggravation of endocarditis from the strain and, had the heart been affected from the effort, immediate prostration or intense discomfort would have developed.

M.D., New Jersey.

Answer.—In the absence of cardiac symptoms per se, namely precordial pain, dyspnea and severe palpitation, there is no clear basis for the opinion that the physical strain in this case aggravated "heart disease with endocarditis." Generalized abdominal pains and weakness are not cardiac symptoms. If there had been a high degree of valvular involvement of rheumatic or syphilitic origin, it is possible that severe physical strain might have caused the myocardium to fail or even might have produced, as it rarely does, rupture of a valve cusp or of the chordae tendineae; but there is no evidence that such occurrences took place here. It is uncommon for an endocarditis to follow simple physical strain.

CONTRACEPTION SIX YEARS AFTER MENOPAUSE

To the Editor:—I have been asked the question "Is there need for contraceptive measures to be taken by a woman aged 57 who has not menstruated during the past six years? Without such measures what are the chances of her becoming pregnant?" M.D., New York.

Answer.—There is no need for such a patient to use contraceptive measures because a pregnancy is out of the question. As far as is known there is no case on record of a gestation having occurred under these circumstances.

PRINCIPLES IN THE MANAGEMENT OF EXTERNAL FECAL FISTULAS

CLAUDE F. DIXON, M.D.
and
RAYMOND E. BENSON, M.D.
First Assistant in Surgery, Mayo Clinic
Rochester, Minn.

Fecal fistulas are fairly frequently encountered by those engaged in the practice of surgery. Usually they arise as an unexpected and distressing complication of abdominal operations. Sometimes they heal spontaneously and all that is required of the surgeon is "masterly inactivity." The eradication of others, however, may be an extremely difficult task—one that will tax the skill of the most resourceful operator. There are certain well founded principles which may be used as a guide in the treatment of fecal fistulas and which may expedite the task of the physician and the recovery of the patient. To ignore these rules is often to invite poor results or disaster and, as many of them have not been clearly elucidated before, we will set them forth in the following paragraphs.

The few statistical deductions of this report are based on an analysis of data on 65 consecutive cases of persistent external fecal fistulas in which the patients were surgically treated by the senior author in the period from January 1942 to December 1944 inclusive. Mayo and Schlicke[1] and Lichtman and McDonald[2] have reported data on the cases observed at the Mayo Clinic prior to 1942.

Fecal fistulas may be classified as internal or external. In the former group there is no communication with the body surface, the fistula being an abnormal communication between two hollow viscera. This study is not concerned with internal fecal fistulas except as they are found in association with the external type. External fistulas are those which terminate on the body surface. Such fistulas may have their origin in any of the hollow abdominal viscera, but the present review is confined to a group known as external fecal fistulas. The term "fecal" connotes origin from that portion of the gastrointestinal tract in which the contents have the characteristics of feces. Such fistulas arise from the distal portion of the ileum and from the colon, the jejunum and the duodenum being excluded. Most of the external fecal fistulas of the present series terminated on the abdominal wall, but in occasional instances the external orifice was found in the lumbar, sacral, gluteal or thoracic areas or on other portions of the body surface.

The great majority of the fistulas in this series had as their point of origin the ileum, cecum or sigmoid. This fact is explained by the frequent predilection for these regions of chronic granulomatous disease processes such as regional enteritis and perforating diverticulitis.

Spontaneous fecal fistulas which arise without any antecedent surgical intervention are uncommon. Only 2 such cases were found in this series. In 63 (97 per cent) the fistula followed some type of operative procedure. In a few the original operation had been performed several to many months prior to the advent of the fistula and for a condition which could not have been etiologically related. The 63 postoperative fistulas were all accidentally produced. Cases in which enterostomy or colostomy was performed or other types of enteric stomas were intentionally produced are not included here, our observations regarding the surgical management of these having been recorded elsewhere.[3]

THE AVOIDANCE OF EARLY OPERATION

It is almost universally wrong to attempt to repair an external fecal fistula surgically shortly after its inception. Better results will be obtained if a period of waiting and conservative treatment is indulged in first. Delayed operation is usually not advisable in cases of fresh, penetrating gunshot or stab wounds of the abdomen. If, however, a person who has sustained a penetrating abdominal injury is not seen for many hours or several days after the injury and a fecal fistula has developed, it is best not to attempt to repair the fistula immediately. Other conditions may be present which will require early surgical intervention, but the fistula per se is best left alone. This is likewise true for postoperative fecal fistulas and those which arise spontaneously.

There are several reasons for this. The fact that an external fistula exists usually indicates that the perforation in the bowel which is the point of origin and the fistulous tract are well "walled off" from the general peritoneal cavity by plastic exudate, adhesions, omentum, intestinal loops and other intra-abdominal structures. The danger of spreading, generalized peritonitis is not great. Early in the course of a fecal fistula there is an acute perifistulous inflammatory reaction which involves all the structures which surround the tract. Attempts at repair during this acute inflammatory stage break down the surrounding protective zone of adhesions and omentum, spread the infection and may result in generalized peritonitis and death. It should also be noted that during the early stages the surrounding edema, infection and inflammatory reaction so obliterate the normal landmarks that dissection of the fistulous tracts and recognition and mobilization of the affected segments of bowel are extremely difficult. Even if the

dissection can be carried out successfully, it is often found that the intestinal wall for a considerable distance proximal and distal to the point of origin of the false opening is edematous, friable and inflamed. Suturing of such intestine is difficult and unsatisfactory, for often the sutures will not hold, the line of closure will separate and the fistula will recur.

Early operation for external fecal fistula is not only fraught with danger and usually unsatisfactory; it is, in addition, often entirely unnecessary. Many external fecal fistulas will close spontaneously with no treatment other than the application of simple conservative measures. Early operation to eliminate the fistula often merely adds insult to the injury already sustained. In 39 per cent of the cases in Deaver's [4] series the fistula closed spontaneously, and in Ray's [5] experience operative procedures were not required in 10 of 11 cases (91 per cent) of fecal fistula following appendectomy. Others [6] have recorded a similar experience.

THE NATURE AND METHODS OF CONSERVATIVE TREATMENT

In the early stages of formation of a fecal fistula there are usually considerable irritation and local inflammation of the peritoneum. In consequence of this, varying degrees of paralytic ileus develop and abdominal distention, constipation, localized abdominal tenderness, vomiting and fever will ensue. The abdominal distention may be contributed to by a subacute mechanical obstruction from the inflammatory mass which surrounds the injured portion of the bowel. Treatment during this phase is best carried out by instituting continuous transnasal intestinal suction, warm applications to the affected area, withholding of food and liquid nourishment and provision of adequate parenterally administered fluid, solution of glucose, and saline and vitamin replacement therapy. Intravenously administered sulfonamide compounds may also be of value, and for this purpose the sodium salt of sulfadiazine may be appropriately used. Infection in the wound is an invariable accompaniment of formation of fecal fistula. Disruption of the wound may occur and, to obviate this, complete rest in bed should be insisted on and the abdominal wall should be reinforced with broad strips of strong adhesive tape and an abdominal binder. Blood transfusions are often of value as a supportive measure and to combat secondary anemia.

In a few to several days the fever and ileus usually subside, general improvement occurs and the subacute stage of the fistula commences. Intestinal drainage can now be discontinued and the peroral intake of fluids and food gradually and cautiously increased. Considerable amounts of purulent material and feces may drain from the wound. Parenterally administered sulfonamide compounds can be dispensed with and other types of treatment instituted. Efforts now are directed toward eliminating the residual perifistulous inflammation, decreasing the passage of intestinal contents through the fistula and improving the patient's general condition. The local application of heat in the form of warm, moist dressings or more intensively by means of diathermy may well be continued, for the value of heat in hastening the resolution of inflammatory processes has often been demonstrated. The infectious nature of the feces can be reduced by the administration of succinylsulfathiazole by mouth. Unfortunately, however, this drug often causes the feces to become liquid. The liquid feces drain readily through the fistulous opening and may result in great excoriation of the skin unless special precautions are taken. To make the intestinal contents more solid, camphorated tincture of opium or bismuth preparations are commonly employed, but probably better for this purpose is one of the psyllium seed products, which absorb intestinal water.

The problem of prevention and treatment of excoriation and erosion of the skin and abdominal wall by fistulous discharges is especially great when the intestinal contents so evacuated come from the ileum and upper segments of the small intestine. For these purposes many ingenious types of pastes, salves, suction appliances and plugs of various sorts have been devised to protect the skin and abdominal wall. In our experience the best results have been obtained with the local application of aluminum paste or, in occasional cases, kaolin paste. The latter substance can be built up around the opening of the fistula to form a cuplike receptacle which collects the dejecta from the fistula and does not allow them to come in contact with the skin.[7] Continuous catheter suction using an electrical suction device will remove the discharges immediately and may often be of benefit. When the skin is soft and macerated, the drying effect obtained by exposing the wound and applying mild, dry heat as obtained from an ordinary electrically lighted hood will often be of aid. In those instances in which excoriation of the skin is especially severe, it is sometimes wise to place the patient in the prone position on a Bradford frame for a few days in such a posture that the external opening of the fistula is in the most dependent position.[8] An opening through the frame permits drainage to take place into a container placed beneath the patient, and soiling of the skin and surrounding tissues is completely prevented.

Chewing gum and various plugs and buttons have all been suggested at one time or another as a means of occluding the fistulous opening. Successes in obtaining spontaneous closure have been obtained with each of these, but in general they are of very limited value. Fecal fistulas heal by contracture of scar tissue and consequent obliteration of the lumen, and it would seem, at least in some instances, that the insertion of a foreign body into the tract would serve simply to prevent the desired contracture and healing. A more universally applicable way of decreasing the flow of excreta from a fistula is by increasing the consistency of the feces and insuring that the bowel distal to the origin of the fistula is patent.

If after twelve weeks to six months of conservative treatment the fistula still persists and no further progress toward spontaneous closure is demonstrable, it must be classified as a late chronic or persistent fecal fistula and the line of therapy must be again altered.

THE MANAGEMENT OF PERSISTENT FECAL FISTULAS

The Determination of Etiologic Factors and the Site of Origin.—Just as there is a primary cause for all fecal fistulas, there is likewise a cause for their persistence. Nature is kind and will gradually resorb the products of inflammation and eliminate most fistulas unless insurmountable obstacles exist. In some instances the primary cause and the reason for persistence of the fistula are not the same. A recently observed case illustrated this. The primary cause of the fistula was trauma to the cecum during appendectomy. Persistence of the fistula was, however, apparently due to retained foreign bodies (steel surgical needle and cotton fibers) in the tissues of the abdominal wall. In other instances the primary and secondary factors are the same. This is exemplified by instances of diverticulitis with fistula formation. In these the original perforation in the bowel is due to diverticulitis, and the persistent fecal fistula is also often attributable to continued peridiverticular inflammation and disease of the intestine.

In all cases of fecal fistula the efforts of the physician should be directed toward determination of the cause of the fecal drainage as soon as the patient's condition permits the necessary examinations. As nearly as could be determined, the factor responsible for persistence of the fistula in the 65 cases of this series was as follows: Continued fecal drainage is in many cases attributable to primary disease of the intestine. In this group are included diverticulitis (12 cases), regional enteritis (12 cases), intestinal cancer (7 cases), chronic ulcerative colitis (5 cases), tuberculous[9] enteritis (2 cases) and actinomycosis (2 cases). In other instances the primary disease is not in the intestine but within the peritoneum or adjacent structures. In this classification are included pelvic inflammatory disease (5 cases), pelvic inflammatory disease with associated osteomyelitis (1 case), tuberculous[9] abscess, primary focus extraintestinal (1 case), retained foreign bodies with osteomyelitis (1 case) and osteomyelitis (1 case). The last group of fecal fistulas is composed of those the persistence of which is attributable to pathologic conditions within the fistulous tract itself or in the abdominal wall. There were 5 cases in which the contraction of scar tissue incident to attempts at healing of the fistula resulted in encroachment on the lumen of the bowel at the site of origin of the false communication to such an extent that mechanical factors prevented healing of the tract. In 2 cases recognizable and removable foreign bodies were encountered in the tract or abdominal wall.

There remains a group of 9 cases in which no clinical or pathologic evidence (using ordinary methods) of the cause of the fistula could be determined. The studies of Feinberg,[10] German[11] and Lichtman and McDonald[2] have given a clue as to the possible cause in this group. These investigators have found talc, cotton fibers, lycopodium granules and other minute foreign bodies in intra-abdominal granulomas and fistulous tracts. It may well be that such particulate foreign material was responsible for the persistence of many of the fistulas classified here as indeterminate. It is also possible that in many of the other cases a multiplicity of etiologic factors were present. The grouping here includes only the one most important factor for each case. In many instances there may have been in addition to the primary factor other causes such as retained particulate matter which contributed to the persistence of the fistula.

Careful general examination should always be performed and roentgenograms of the affected regions should be searched for radiopaque foreign bodies. When the fistula arises in the lower left portion of the colon, proctoscopy may afford valuable information. Careful inspection and examination of the fistulous opening and surrounding area and microscopic examination and culture of the discharge from the fistula are of paramount importance. The characteristic "sulfur bodies" of actinomycosis should always be sought and in occasional instances special examinations for other fungi, tubercle bacilli and pathogenic amebas are in order. The most valuable preoperative test, however, is the roentgenographic examination of the intestine following the administration of barium. By this means disease of the bowel can be recognized and in many instances the site of origin of the fistula can be determined. In some cases injection of a radiopaque liquid into the fistulous tract followed by roentgenograms will give information as to the origin, length and ramifications of the tract.

The Determination of Patency of the Bowel Distal to the Fistula.—It is foolish to attempt to close a fistula if the bowel distal to the point of origin is subacutely or completely obstructed. Intestinal obstruction will certainly result, and recurrence of the fistula will surely follow. When an obstruction is found in the bowel distal to the point of origin of a fistula, this must first be relieved. If this is done the fistula will often heal spontaneously, for in this type of case fistulas often depend for their continued existence on increased intraluminal pressure in the bowel secondary to obstruction.

Essentials in the Preoperative Care of Persons Who Are to Undergo Surgical Treatment for External Fecal Fistulas.—Before making a direct surgical attack on a fecal fistula it is apparent from the foregoing discussion that several conditions should, if possible, be met. The first requisite is to determine the cause of the persistent fecal fistula; the second, to know from what segment of the intestine the false communications have their origin. The third requisite is the determination of the patency of the bowel distal to the fistula and, fourth, an adequate trial at conservative management should have been made.

There are several other conditions which it is desirable to meet before instituting definitive surgical treatment. The general condition of the patient should be improved as much as possible. Persons who have persistent external fecal fistulas are often debilitated, weak, anemic and undernourished. It is not amiss to hospitalize a patient for several weeks of preoperative preparation. The nutritional status can be improved with a high caloric, high protein diet. Appropriate medications and blood transfusions will correct anemia when it exists. When derangements of electrolyte balance are present, they should be corrected and vitamins should be given in amounts sufficient to overcome any tendency toward deficiency.

It must next be determined that all evidences of acute inflammation around the fistulous tract and in the abdominal wall have subsided. If such is not the case, conservative measures as previously outlined may be continued for a while longer.

[9] Histologic diagnosis only.

[10] Feinberg, Robert: Talcum Powder Granuloma, Arch. Path. **24:** 36-42 (July) 1937.

[11] German, W. M.: Dusting Powder Granulomas Following Surgery, Surg., Gynec. & Obst. **76:** 501-507 (April) 1943.

For at least three days and preferably for five to six days before operation succinylsulfathiazole should be administered in adequate doses. The usual procedure is to give 4 Gm. of this drug every four hours for the first twenty-four hours and 2 Gm. every four hours thereafter. The last dose is given approximately six hours before the time of operation. For three to four days before operation a high carbohydrate, very low residue type of diet, gentle catharsis with a saline laxative and repeated saline enemas are employed to reduce the amount of retained fecal material. During the twenty-four hours immediately preceding operation enemas and laxatives are discontinued, 2 fluidrachms (7 cc.) of camphorated tincture of opium is given every four hours and aspirations of the rectum are performed.

If the patient can meet all the foregoing requirements and is properly prepared, the surgeon will often choose to make a direct attack and resect the fistula and underlying diseased parts, for by so doing the best chances for an early and permanent cure are obtained. Certain circumstances will alter the plan, however, and experience may indicate the preferability of conservative surgical procedures.

The Types of, and Indications for, Conservative Surgical Treatment, Curettage of the Fistulous Tract.—If after an adequate trial of conservative medical management all evidences of active inflammation about the tract have subsided, fecal drainage is minimal or almost entirely absent and no significant disease of the intestine or perifistulous structures can be demonstrated, simple curettage will remove any epithelial lining of the tract and may stimulate healing sufficiently to cause closure of the fistula. It is occasionally successful. Cases in which treatment was by curettage were considered nonsurgical and not included in the present series.

Short-Circuiting or Sidetracking Procedures: Short-circuiting or sidetracking procedures are a very valuable form of treatment for persons who have persistent external fecal fistula. In general they serve the purpose of aiding patients who cannot meet the conditions essential to a direct attack on the fistula. They are useful as a preliminary procedure for those in whom a persistent acute or subacute inflammatory reaction in the intestine and about the fistula will not subside with the conservative medical treatment, for diversion of the fecal stream will aid resolution of the inflammatory process. They are also useful for those whose general condition is so poor that a more extensive operation would be unduly hazardous. A preliminary short-circuiting procedure may allow a striking improvement in general health. Short-circuiting procedures are also used as a palliative procedure in cases of large, perforating, inoperable cancers of the intestine in which an external fecal fistula has formed. Occasionally a short-circuiting procedure will turn out to be a form of definitive treatment and will result in complete subsidence of the fistula.

The purpose of short-circuiting and sidetracking procedures is to divert the fecal stream from the segment of intestine which gives origin to the fistula. When the fistula originates in the terminal portion of the ileum, the cecum, the ascending colon or the hepatic flexure, this can be accomplished by ileocolostomy. The abdominal incision for this operation should be made at a distance from the infected region around the fistula.[12] Two types of ileocolostomy are commonly employed. In the exclusion type the ileum is transected proximal to the diseased region, the distal end is inverted and the proximal end is anastomosed to the colon at a point distal to the diseased region (usually to the transverse colon). The side to side type of anastomosis is preferable, but end to side union may also be employed. In the ordinary type of ileocolostomy (ileocolostomy in continuity) the ileum is not divided. A simple side to side anastomosis is effected between a segment of ileum above the diseased region and the colon distal to the involvement.

What results can be expected from these procedures? In the occasional case in which there is no disease in the underlying bowel, spontaneous subsidence of the fistula will result and no other treatment will be necessary. When the fistula arises from a segment of ileum or cecum which is the site of regional or tuberculous enteritis or chronic ulcerative colitis of the regional type, a sidetracking procedure is usually not curative. Its main advantage has been, in the experience of the senior author, that it aids in improving the patient's general condition and makes the necessary resection less formidable by dividing it into stages. This point is, however, strongly contested by some[13] who feel that regional enteritis with fistulas will heal completely with the performance of an exclusion type of ileocolostomy alone. Further study will be required to settle the point.

Ileostomy is a type of sidetracking operation which is the procedure of choice in the treatment of persons who have external fecal fistulas arising from chronic ulcerative colitis of the rectum, sigmoid or entire colon. It does not eliminate the fistulas, but by diverting the fecal stream from the diseased large intestine it reduces the amount of irritating discharge from the fistulas and great improvement in the patient's general health may accrue. Second stage resection of the diseased segments, usually the entire colon, is necessary to eradicate the fistulas and the disease.

When the fistulas arise from the left portion of the colon, proximal colostomy may be used as a sidetracking procedure when activity of the disease or the patient's condition does not permit primary resection. The stoma should be placed far proximal to the diseased region so that, if resection is later undertaken, the stoma will not interfere with mobilization of the left portion of the colon. Colonic stomas are easily and conveniently established in the transverse colon, and this site is preferred whenever possible. Perforating diverticulitis with external fecal fistulas deserves especial mention here. In this disease the conditions necessary to permit a primary resection of the fistulas and diseased bowel can seldom be met without the performance of a preliminary short-circuiting procedure (transverse colostomy). Diverticulitis produces a very acute, phlegmonous and indurated inflammatory reaction which is very slow to subside. Even after the fecal stream has been diverted, conservative measures must be employed for at least three months, and often it is six months or one year before the inflammatory reaction has subsided sufficiently to enable the surgeon to proceed with resection.

Methods of Resection in the Treatment of Persistent External Fecal Fistulas.—The Type of Incision: The incision should encircle and excise the fistulous tract

(fig. 1). Lockhart-Mummery[14] has advocated a remote incision made through a clean field at a distance from the external opening of the fistula, but there are several disadvantages to this. In the former type the openings of the fistula are encircled by a purse string suture before the incision is made, and if care is taken not to incise the tract accidentally during the dissection there is little contamination. In the remote type of incision the tract must be transected from the inside at the level of the peritoneum. This leaves intact the segment of the tract which traverses the layers of the abdominal wall. The infected contents of this portion of the fistula may spill into the peritoneal cavity. Other objections to the remote incision are that the raw surface left after the fistula has been dissected free from the abdominal wall must be reperitonealized from the inside This task is often difficult when the incision is remote, but it is accomplished easily with the routine closure of the abdominal wall when the original incision encircles the fistulous tract With the remote incision it is advisable at the conclusion of the operation to excise the portion of the tract left in the abdominal wall and the surrounding diseased tissues This procedure is accomplished more satisfactorily at the time of the initial incision

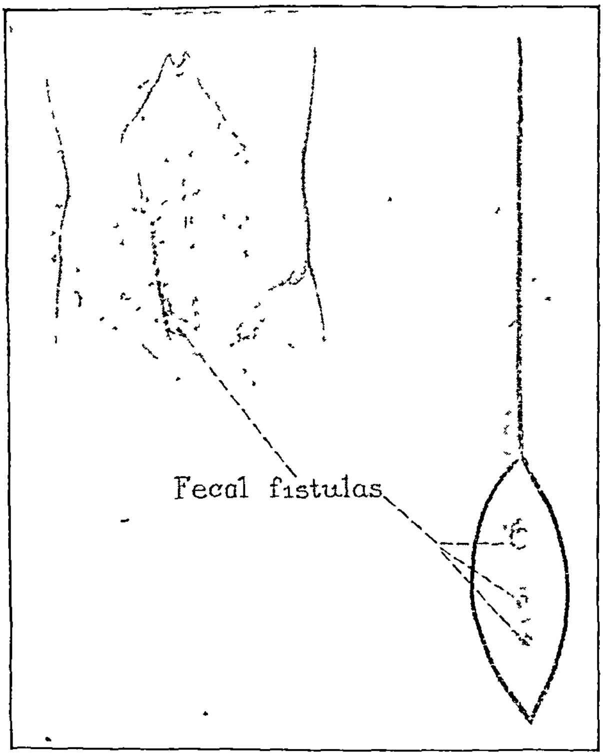

Fig 1—Left, three fistulous openings in lower end of right paramedian scar Right, the incision (indicated by solid line) encircles and excises the fistulas

In some cases the external openings of the fistula will be in the gluteal, lumbar, sacral or thoracic region or in such a position on the abdominal wall that they cannot be included in the incision. For these there is no alternative to the use of a remote incision. In other cases in which there are multiple, widely separated openings all of which cannot be included in the incision, the remaining tracts must be dissected free from the intraperitoneal aspect.

Mobilization and Inspection of the Intestine: Coffey[15] and others have discussed extraperitoneal procedures in the surgical treatment of external fecal fistulas. These have a field of usefulness in the elimination of colonic or enteric stomas or the occasional accidentally produced fistula in which the skin and mucous membrane of the bowel are close together or in continuity. In the great majority of cases of persistent fecal fistula, however, and in all cases in which disease of the underlying intestine is suspected or known to be present, the peritoneum should be opened and the intestine mobilized so that it can be thoroughly examined by direct inspection (fig. 2). With proper precautions against contamination the danger of peritonitis is minimal, for the peritoneum has been well vaccinated against the pathogenic organisms present and the use of the sulfonamide compounds affords extra protection.

The Extent of the Resection: All diseased tissue must be removed. This includes not only the fistulous tract and the surrounding infected tissues of the abdominal wall but all the diseased bowel and other infected and useless intraperitoneal structures (fig. 3). In some cases it will be found on inspection that no significant disease of the intestine is present. For these cases simple resection of the fistulous tract, excision of a small rim of normal intestinal wall around the origin of the tract and closure of the opening are all that it is necessary to do In other cases there is a scar tissue contracture of the bowel at the site of the origin of the fistula, and after excision of the tract a small plastic procedure will be necessary to maintain an adequate intestinal lumen. These two types of procedures were performed eighteen times in the present series.

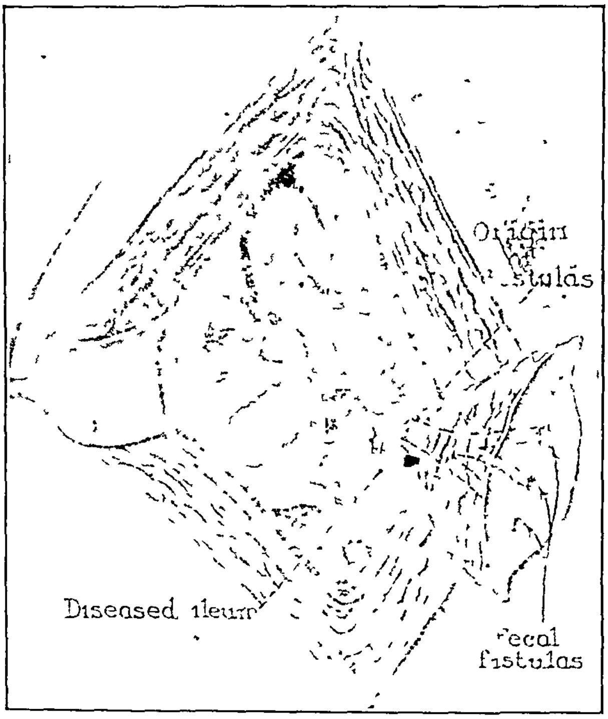

Fig 2—The peritoneum is opened and the bowel is mobilized, revealing the origin of the fistulas from a diseased terminal ileum

In the majority of cases of this series (35 cases) disease of the underlying intestinal loops was demonstrable and resection was undertaken. In 21 cases resection of varying lengths of ileum and the right side of the colon was necessary. This type of operation is usually performed in one stage (19 of 21 cases), intestinal continuity being regained by simultaneous side to side ileocolostomy. There were 9 resections of portions of the left side of the colon. All of these operations were performed in multiple stages as extraperitoneal resections with subsequent closure of the resulting colonic stoma or with a preliminary sidetracking operation followed by resection. In 1 case primary disease of the ileum (regional enteritis) had perforated into and involved the sigmoid colon. In another instance a primary carcinoma of the sigmoid, in addition to forming an external fecal fistula, had secondarily involved the ileum extensively. In both of these cases double resection of sigmoid and ileum was performed. In 3 cases the underlying disease and resulting fistulas were so extensive that removal of almost the entire colon, leaving only the rectum and lower part of the sigmoid, was necessary.

[14] Lockhart-Mummery, P.: Methods of Closing Fecal Fistulae, Surg., Gynec. & Obst. 29: 312-314 (Sept.) 1919

[15] Coffey, R C Remote or Indirect Subperitoneal Drainage in the Extraperitoneal Closure of Persistent Fecal Fistulae, Ann. Surg. 45: 827-835 (June) 1907

In 13 cases one or more internal fistulas were found coexistent with the external communication. When this situation is encountered, the internal fistula must be resected also in order to effect a cure. In 10 cases enteroenteric fistulas were found. In some instances these were undoubtedly of benefit to the patient while the disease process was still present, for they represented spontaneous short circuits around diseased and obstructed segments of intestine. Enterovesical fistulas were encountered in association with external fecal fistula 2 times. For these, in addition to resection of the fistula and diseased bowel, it is necessary to excise the communication between the bowel and the urinary bladder. In a previous report we discussed the management of such cases and indicated the desirability of temporary suprapubic cystostomy when resections of the bowel and the bladder are performed simultaneously.[16] In 1 additional case external fecal and enterovaginal fistulas coexisted.

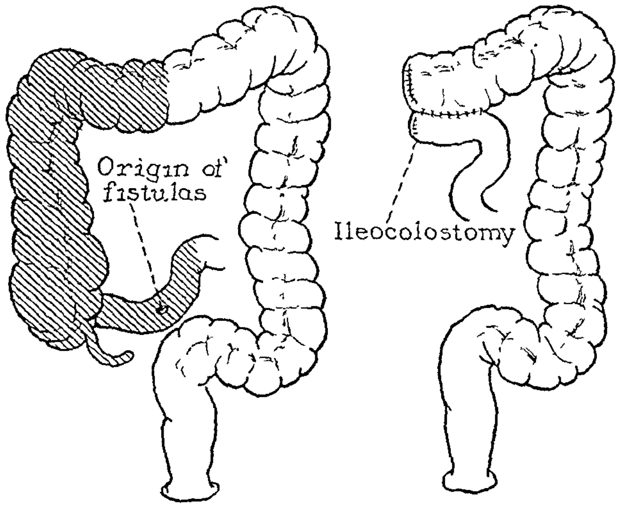

Fig. 3.—Left, shaded area indicates amount of bowel to be resected Right, intestinal continuity regained by ileotransverse colostomy (side to side).

At the conclusion of the operation 5 Gm. of sulfathiazole or sulfanilamide is dusted intraperitoneally and a small additional amount is sprinkled in the incision. It is also often advisable to insert a soft rubber intraperitoneal drain.

Postoperative Care.—Whenever there is a suture line in the intestine which is not protected by a proximal colonic stoma or other type of artificial vent, the bowel should be kept well decompressed by transnasal intestinal suction for the first four to five postoperative days. If at the end of this time the patient tolerates having the tube clamped without distress, it may be removed and the peroral administration of fluids and food gradually increased.

As an additional prophylactic measure against infection, parenteral sulfonamide therapy may be employed. It has been our practice to administer slowly 5 Gm. of sodium sulfadiazine diluted in 2,000 cc. of isotonic solution of sodium chloride subcutaneously, starting twenty-four hours after the operation. In this manner a concentration of sulfonamide compound in the blood adequate for prophylactic purposes is maintained by the use of minimal amounts of the drug.

In an occasional case the region of the external opening of the fistula will be surrounded by many other old surgical incisions and extensive scarring. In such instances it may be necessary to sacrifice considerable skin and subcutaneous tissue. As a result there may be some tension on the skin suture line and, the blood supply to the region already being poor, some danger of necrosis exists. To obviate this, refrigeration of the wound by the continuous application of ice bags may be used. In several instances we have thought that the procedure was of definite benefit. It also frequently produces gratifying alleviation of pain in the incision.

The remainder of the postoperative treatment does not differ materially from that of the ordinary patient who has undergone an intestinal operation.

Special Considerations.—One of the types of persistent external fecal fistula in which treatment is difficult is that in which the patient is a woman and the original pathologic condition was pelvic inflammatory disease with pelvic peritonitis. Many loops of intestine may be firmly intricated in a mass of pelvic adhesions and large chronic tubo-ovarian abscesses and other inflammatory collections may be encountered. To dissect out the fistulous tract, release the intestine, remove the diseased tissue and restore some semblance of normality to the pelvis is indeed often a difficult task. Six such cases were encountered in the present series. For all cases of external fecal fistula, but especially those in which the primary pathologic change is pelvic inflammatory disease or diverticulitis of the sigmoid with perforation, the importance of prolonged conservative treatment until all evidences of acute inflammation have subsided cannot be stressed too much.

External fecal fistulas which pass through bone are extremely refractory to treatment. The difficulty lies in fulfilling the principle of removing all diseased tissue. Not only are the removable soft tissues involved but bony structures are infected as well (osteomyelitis) and these can seldom be completely extirpated. Our usual procedure has been to dissect out the tract, transect it at the point of entrance into bone, remove all diseased soft tissues and thoroughly curet the osteomyelitic tract, removing all possible sequestrums. A preliminary or simultaneous proximal artificial stoma is established to defunctionalize the segment of intestine on which operation is performed. After many weeks or months the stoma may be closed and intestinal continuity reestablished. Even with the most elaborate precautions, however, poor results are common. The mechanism of recurrence of the fistula seems to lie in the development of an abscess between the proximal end of the osteomyelitic tract and the intestine. This ruptures into the bowel and the bony tract to reestablish the fistula. Three such cases are included in the present series. In 2 of these preoperative and postoperative penicillin therapy seemed to be of some value.

---

[16] Dixon, C. F., and Benson, R. E.: Unpublished data.

Enteroabdominal actinomycosis with formation of external fecal fistula is ordinarily not amenable to surgical treatment. When the disease is so extensive that fistulas have formed, it is virtually impossible to eradicate it completely by surgical methods and recurrence is prompt. In 2 cases included in the present series of 65 cases in which treatment was surgical, incision and drainage of intra-abdominal abscesses only were performed. One of the patients showed no improvement with penicillin therapy; the second has shown some improvement but after months of intermittent therapy with penicillin still has active disease. A third nonsurgical patient, not included in the present series, who had a less advanced stage of the disease showed striking early improvement with intensive penicillin treatment, but insufficient time has elapsed to evaluate the final result.

MORTALITY

In the entire group of 65 cases there were two hospital deaths (3 per cent). One patient who underwent resection of the terminal ileum and right portion of the colon for extensive regional enteritis with multiple external and internal fecal fistulas died on the fourteenth postoperative day of thrombosis of the portal vein. The other patient died of widespread enteroabdominal actinomycosis. Surgical treatment in this case was limited to incision and drainage of abdominal abscesses.

SUMMARY

1. Early operation for the elimination of external fistulas is usually not advisable.
2. Many fistulas close spontaneously with conservative, nonsurgical treatment.
3. In the early, acute stages of formation of fecal fistula, treatment consists in transnasal intestinal suction, warm applications to the affected area and adequate parenteral fluid, solution of glucose, saline solution and vitamin replacement therapy. Parenterally administered sulfonamide compounds and blood transfusions may be of value.
4. In the subacute stage, efforts are directed toward eliminating the residual perifistulous inflammation, decreasing the passage of intestinal contents through the fistula and improving the patient's general condition.
5. Before instituting definitive surgical treatment for chronic, persistent fecal fistulas the following conditions should be met if possible: (*a*) The etiologic factors responsible for persistence of the fistula should be determined; (*b*) the segment of intestine from which the false communications have their origin should be determined; (*c*) it should be known whether the bowel distal to the lesion is patent; (*d*) an adequate trial of conservative management should have been made; (*e*) the general condition of the patient should be evaluated; (*f*) all evidences of acute inflammation about the fistulous tract should have subsided.
6. Conservative surgical treatment, such as short-circuiting or sidetracking procedures, is used when the patient cannot meet the prerequisites for a more extensive, direct surgical approach.
7. In applying resection methods in the treatment of persistent, external fecal fistulas, (*a*) the incision should, when possible, encircle and excise the fistulous tract; (*b*) in most cases best results will be obtained if the peritoneum is opened and the affected segment of bowel is mobilized and inspected; (*c*) all diseased tissue should be removed.
8. The types of persistent external fecal fistulas in which treatment is most difficult are (*a*) those in which the patient is a woman and the original pathologic condition was pelvic inflammatory disease with pelvic peritonitis, (*b*) those in which the fistula arises in a region affected by severe diverticulitis with perforation, (*c*) those in which the fistula passes through bone and (*d*) those in which the fistula is associated with enteroabdominal actinomycosis.
9. In the 65 cases of persistent external fecal fistulas of this series, in each of which treatment was surgical, there were two hospital deaths (3 per cent).

PENETRATION OF PENICILLIN INTO FOCI OF INFECTION

ISADORE E. GERBER, M.D.; GREGORY SHWARTZMAN, M D
and
GEORGE BAEHR, M D
New York

The control of infection by penicillin is generally acknowledged to be dependent on the susceptibility of the bacterial species, the relative resistance of the strain responsible for the infection and the duration of its exposure to a therapeutically effective concentration.[1] To these three factors we would add a fourth, the attainment of a concentration in the blood sufficiently high to secure penetration into dense inflammatory foci in which bacteria are embedded. Very much higher blood levels are necessary to obtain this objective than for simple sterilization of the blood stream.

In order to facilitate the penetration of chemotherapeutic agents into the vegetations of subacute bacterial endocarditis, some clinicians[2] have heparinized their patients. It is doubtful whether the prolongation of the coagulation time of the blood to thirty or sixty minutes has any appreciable effect on the masses of blood platelets and fibrin of which the vegetations of subacute bacterial endocarditis are composed, especially since they are invaded very early by actively proliferating fibroblasts. Autopsies on heparinized patients with subacute bacterial endocarditis have revealed no gross or microscopic evidence to substantiate the hypothesis that heparin in the amounts employed exerts any effect on the structure of the vegetations. We have therefore omitted the administration of heparin in the penicillin therapy of the last 25 patients with subacute bacterial endocarditis and have achieved sterilization of the blood stream and apparently complete

elimination of the infection in the valves in 22 by more careful attention to the attainment of high blood levels of penicillin.

In spite of the fact that penicillin is readily diffusible, it does not penetrate from the blood stream into the normal spinal fluid, tears, breast milk and saliva or into the cornea, lens, vitreous humor, brain, dura, nerves and bone marrow unless huge amounts are administered parenterally and extremely high blood levels are attained. In the presence of an inflammatory process with increased vascularization, slight penetration can be accomplished into these tissues. Although only a trace is found in the normal spinal fluid after parenteral doses as high as 300,000 units, the blood-brain barrier becomes permeable during meningitis to small but therapeutically effective concentrations

TABLE 1.—*Coefficients of Resistance to Penicillin of Organisms Isolated in Twenty-Nine Cases of Subacute Bacterial Endocarditis*

Number of Cases	Organism	Coefficient of Resistance
4	Streptococcus viridans	1
1	Staphylococcus albus	1
8	Streptococcus viridans	2
1	Streptococcus hemolyticus	2
8	Streptococcus viridans	3
2	Streptococcus viridans	5
1	Streptococcus viridans	10
1	Enterococcus	10
1	Streptococcus viridans	20
1	Enterococcus	25
1	Enterococcus	150

Similarly a therapeutic level may be found in the normal aqueous of dogs only after the intravenous administration of a dose comparable to 900,000 units in man, yet effective concentrations are achieved after much smaller doses in the presence of a corneal ulcer or abrasion[3]

On the other hand, some organs and tissues such as the extraocular muscles and even some less vascularized tissues like the sclera and conjunctiva manifest a selective absorption of the drug and may at times contain a concentration greater than that of the blood Infections in well vascularized soft tissues respond to concentrations of the drug that are completely ineffective in relatively avascular hard tissues such as bones[4]

TABLE 2—*Dose of Penicillin Recommended for Infections with Organisms of Varying Coefficients of Resistance*

Coefficient of Resistance of Infecting Organism	Penicillin Dose Recommended by Intramuscular Injection Every Three Hours	Peak Blood Concentration to Be Achieved *
1	15,000	0.5
2 to 3	25,000	1.0
3 to 5	50,000	2.0
5 to 10	100,000	6.0
10 to 20	200,000	11.0
20 to 30	300,000	16.0

* In units per cubic centimeter of blood serum Peak is obtained about twenty minutes after intramuscular injection

It has been the general experience that much larger doses and much higher blood levels must be maintained to control infections in tissues with a relatively poor blood supply. Our own experience would indicate that there may be other tissue barriers as well as the degree of vascularization of an infected focus which determine the absorption capacity of a tissue.

It is still the generally accepted practice to resort to continuous intravenous or intramusucular therapy in severe infections with bacteremia and to vary the total daily dose, depending on the in vitro resistance of the organism. This technic results ordinarily in the maintenance of a uniform blood level of sufficient height to accomplish sterilization of the blood of bacteria of comparatively low resistance, but it may fail to eliminate the more resistant bacteria and those embedded in the primary focus, i e in the vegetations of subacute bacterial endocarditis, in a thrombophlebitis or in an osteomyelitis. Under these circumstances the blood may again become infected shortly after discontinuance of prolonged continuous intravenous or intramuscular therapy as the result of outgrowth of bacteria from the primary focus In our experience a total daily dose of penicillin may often be more effective in eradicating such primary foci of infection if it is given in divided doses of large size rather than as a continuous intravenous or intramuscular drip.

Table 1 illustrates the difference in the penicillin resistance of the bacteria isolated from 29 cases of subacute bacterial endocarditis. Employing the standard Staphylococcus aureus H strain for the measurement of blood levels of penicillin, we arbitrarily established the coefficient of resistance of this organism to penicillin as unity. The penicillin resistance of the isolated organisms is expressed in terms of comparison to the standard The minimum penicillin blood concentration necessary in a given case is estimated by multiplying the coefficient of resistance of the infecting organism by 0.16 unit, the minimal effective level established for the standard strain of staphylococci by Keefer.

TABLE 3—*Penicillin Blood Level Obtained by Continuous Intravenous Infusion*

Total Daily Dose, Units of Penicillin	Average Range of Blood Levels,* Units per Cc of Blood Serum
100,000	0.1 to 0.2
200,000	0.2 to 0.4
500,000	0.8 to 1.2

* These figures represent an average of at least ten series of determinations, with from two to five determinations in each series

We have outlined in table 2 the peak concentrations which seem, in our clinical experiences, to be required for the treatment of infections with organisms with varying coefficients of resistance.

In our early experiences with penicillin, continuous intravenous administration was employed to obtain constant blood levels of sufficient height to exceed the estimated resistance of the infecting organism The blood levels obtained by this method, and by continuous intramuscular drip, are listed in table 3.

Although a favorable response was obtained in many infections, a number of therapeutic failures were encountered in spite of the fact that the blood levels were consistently higher than required in vitro to match the coefficient of resistance of the infecting organism Autopsies in 2 cases indicated that sterilization of the underlying infected focus, such as valvular vegetations in subacute bacterial endocarditis, or infected thrombi, had not been achieved

The much greater rise (and fall) of the blood level after single intramuscular injections of various amounts of penicillin[5] are recorded in table 4. Occasional discrepancies were encountered, for example when the blood level of penicillin after the intramuscular injection of 100,000 units in a single dose failed to rise above 2 units, although the usually observed peak was 6.6 units. The reason for such discrepancies has not been determined. It does not seem to depend on the volume output of the urine, nor is the discrepancy constant in the same individual.

Table 4.—*Penicillin Blood Level Obtained After a Single Intramuscular Injection* *

Amount Injected, Units of Penicillin	Time After Injection: Units per Cc. of Blood Serum			
	20 Min.	40 Min.	60 Min.	120 Min.
15,000	0.5	0.2	0.14	Trace
20,000	0.8	...	0.3	0.06
25,000	1.0	0.8	0.6	0.1
30,000	1.3	...	0.8	0.13
40,000	2.0	1.3	1.0	0.4
50,000	2.0	1.5	1.3	0.6
100,000	6.6	4.0	2.5	1.0
200,000	11.4	6.6	4.3	1.2
[illegible]00,000	16.0	13.0	9.5	2.3

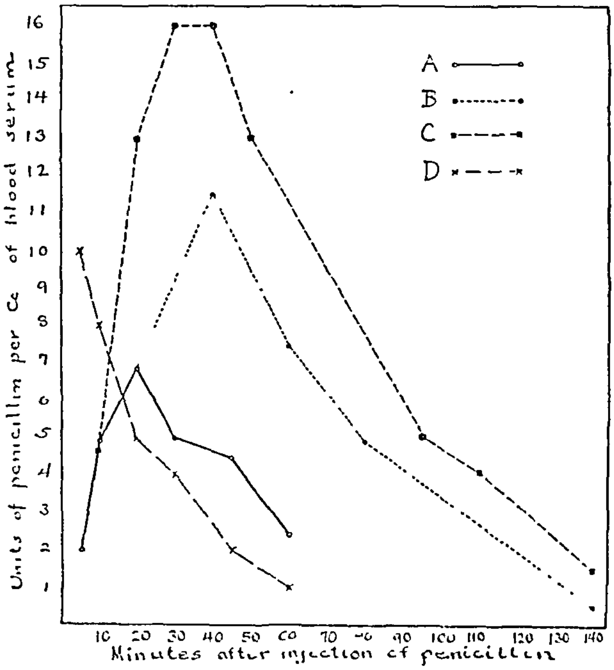
* These figures represent an average of at least twenty-five series of determinations, with from three to six determinations in each series. The figures are only averages and do not indicate the range. The variations in some instances were wide, but on the whole the averages listed represent a fair picture of the blood level which may be anticipated with the various doses employed.

Our clinical experience seemed to warrant the conclusion that the repeated exposure of bacteria with a very high coefficient of resistance to high peak concentrations of penicillin in the blood, even though of short duration, are often of greater therapeutic efficacy than continuous blood levels at lower concentrations. This has been true especially under conditions in which the bacteria are in deeply situated foci of infection, as on the heart valves, where extremely high peak levels are necessary to secure penetration of therapeutically effective concentrations. In subacute bacterial endocarditis both the continuous intravenous or intramuscular injection of 200,000 to 500,000 units a day and the intermittent intramuscular injection of the same total amount in divided doses every three hours for four or five weeks are equally efficacious in controlling the infection permanently when the infecting organism is of relatively low resistance (one to three times the resistance of the standard strain of Staphylococcus aureus H). Therapeutic failures were encountered after the continuous as well as intermittent injection of penicillin, when the infection was due to organisms (Streptococcus viridans or Enterococcus) which were five to twenty times as resistant to penicillin as the standard test organism. In these patients the blood stream is usually sterile during the four weeks while therapy is being given, but the bacteremia may recur soon after treatment is discontinued. These therapeutic failures were attributed to the fact that only surface sterilization of the vegetations had been achieved.

Because of this experience we altered our treatment of subacute bacterial endocarditis by employing only intermittent intramuscular injections, giving 25,000 to 50,000 units at three hour intervals, supplemented when necessary with additional "booster doses" of 50,000 or 100,000 units several times a day. This treatment schedule is continued for four or more weeks. When the infecting organism responsible for the bacteremia is exceptionally resistant (coefficient of resistance of 5 to 20) we have been more successful with the use of supplementary "booster doses" of 100,000 or 200,000 units every twelve hours, in addition to routine intramuscular injections of 50,000 units at three hour intervals. More recently we have increased the routine dosage for these patients to 100,000 units every three hours for five weeks.

In a patient with endocarditis due to an enterococcus with a resistance coefficient of 150, we have succeeded in clearing the blood of bacteria only by administering 1,000,000 units every three hours with "booster doses" of an additional 1,000,000 units twice a day, a total daily dosage of 10,000,000 units. Although the blood stream was free from bacteria throughout the five weeks of therapy, permanent sterilization of the vegetations was not achieved and blood cultures were again positive within a week after cessation of treatment.

Of 29 patients with subacute bacterial endocarditis treated by us with penicillin, 6 died of embolism or circulatory failure during or soon after completing therapy and must be regarded as treatment failures. In the 1 patient whose blood stream was sterilized of an Enterococcus with a resistance of 150, the blood infection promptly recurred after the completion of five months of therapy. Three patients required a second course of treatment with larger doses before the blood stream was permanently sterilized. One required a third course of treatment because of recurrence three months after his discharge from the hospital and has now been well for eight months. Twenty-two of the 29 patients in the series have remained well and bacteria free for six to nineteen months since discharge.



Blood levels in units per cubic centimeter of serum after injection of penicillin by intravenous and intramuscular routes: *A*, penicillin blood level curve after the intramuscular injection of a single dose of 100,000 units; *B*, curve after a second single dose of 100,000 units given intramuscularly twenty minutes after the first dose of 100,000, i. e., when the peak concentration of the first dose is obtained; *C*, curve after a second single dose of 200,000 units given intramuscularly ten minutes after the first dose of 100,000 units; *D*, curve after the intravenous injection of a single dose of 100,000 units

In purely local infections without bacteremia, the maintenance of a constant level of penicillin in the blood is not essential. In fact, in subacute or chronic local infections in which the organisms are encased in dense granulomatous tissue it is obviously more important to achieve exceptionally high levels in the blood several times a day so as to favor penetration into the granulomatous area. Whenever possible, the penicillin should also be repeatedly injected in high concentrations directly into such infected foci. As an example, good results were obtained in a patient whose chest was infected with Actinomyces with a coefficient of resistance to penicillin of 50 by administering 500,000 units in two massive doses daily for four weeks. The penicillin blood level twenty minutes after the intramuscular injections of 200,000 units reached 11.4 units, after 200,000 units intramuscularly and 100,000 units into the chest wall, 16 units per cubic centimeter of serum. This therapeutic result probably could not have been achieved if the same total daily dose had been spread thinly over twenty-four hours by a continuous intravenous drip or by frequent small intramuscular injections.

---

[5] Fleming, A.; Young, M. Y.; Suchet, J., and Rowe, A. J. E.: Penicillin Content of Blood Serum After Various Doses of Penicillin by Various Routes, Lancet 2: 621-624 (Nov. 11) 1944.

CONCLUSIONS

1. In our experience intermittent intramuscular injections of large doses of penicillin at three hour intervals seem in general to be more effective in the control of bacteremia and of local infections than continuous intravenous administration of the same total daily amount.

2. The intramuscular administration of penicillin in divided doses has the distinct advantage of producing a higher peak level in the blood intermittently throughout the day, thereby favoring penetration of penicillin into vegetations of acute and subacute bacterial endocarditis and into suppurative thrombophlebitis or other primary sites of bacteremia.

3. To assure penetration of adequate amounts of penicillin into primary foci responsible for bacteremia (i. e. vegetations, thrombophlebitis), additional massive "booster doses" several times a day are often desirable. Such "booster doses" should be five or six times the routine intramuscular dosage which has produced blood levels sufficient to clear the blood of bacteria.

4. Subacute bacterial endocarditis and other chronic infections due to organisms of relatively high penicillin resistance are more advantageously treated with massive doses at frequent intervals throughout the day (every three hours). The minimum duration of therapy of subacute bacterial endocarditis, in our experience, should be five weeks.

5. In purely localized infections with highly resistant organisms, such as Actinomyces, penicillin is best concentrated in a few massive intramuscular doses each day in order to favor penetration by means of exceptionally high peak levels and, if possible, also administered directly into the infected area.

Sanitation in the Environment.—The sanitary control of the environment is the most important foundation stone of a communitywide public health program. The simple sanitary principles for prevention of disease and promotion of community health that may be applied in any community, large or small, are quite elementary, yet they are so fundamental that they must always be the chief concern of the official health service. The subject is so important that the major portion of the early textbooks on preventive medicine and public health were devoted to a description of the details of the application of the principles of environmental sanitation in the community.—Smillie, Wilson G.: Preventive Medicine and Public Health, New York, Macmillan Company, 1946.

SUPRADIAPHRAGMATIC SECTION OF THE VAGUS NERVES

Effect on Gastric Secretion and Motility in Patients with Peptic Ulcer

Complete division of the vagus nerves to the stomach for the treatment of intractable duodenal ulcer in 2 patients was reported by Dragstedt and Owens [1] in 1943. Subsequent reports of additional cases were made by Dragstedt, Palmer, Schafer and Hodges [2] in 1944 and by Dragstedt and Schafer [3] in 1945. At the present time a total of 38 patients with duodenal ulcer, gastric ulcer or gastrojejunal ulcer have been treated in this clinic by this principle. Details of the surgical technic, indications and end results of the procedure will be discussed elsewhere. In 34 of the patients section of the vagus nerves was accomplished by exposing the lower esophagus after a left thoracotomy and dividing the fibers just above the diaphragm.[3] In 4 patients a laparotomy was performed, the triangular ligament to the left lobe of the liver was divided to expose the cardia, the esophagus was mobilized and pulled downward into the abdomen, and the vagus trunks were ligated and divided along the lower esophagus. The postoperative course of these patients has been characterized by complete relief of ulcer symptoms, objective evidence of healing of the ulcers and definite improvement in general health in almost all cases. In a further investigation of the mechanism of these effects, studies have been made on the gastric secretion and motility in a small series of ulcer patients both before and after section of the vagus nerves.

Evidence that an abnormality in the secretion of gastric juice is present in most if not all ulcer patients and that this may cause the lesion and prevent it from healing has accumulated from both the clinic and the experimental laboratory. A part of this evidence has been summarized recently by one of us [4] and need not be reviewed here. Most of the clinical studies on gastric secretion in ulcer patients have been limited to observations on the secretory response to certain specific stimulants, such as the Ewald meal, alcohol or histamine, as compared with normal persons. While considerable variations have been found, patients with duodenal ulcer on the whole and those with gastric ulcer perhaps less so secrete more gastric juice in response to these types of stimuli than do normal persons. The effect has not been found to be sufficiently uniform, however, to be of diagnostic value.[5] Comparatively little attention has been given to the state of activity of the gastric glands in the intervals between meals and to the volume and acidity of the continuous secretion in the absence of any known type of secretory stimulus.

CONTINUOUS OR NIGHT SECRETION OF GASTRIC JUICE

Beaumont and Pavlov are probably mainly responsible for the view that in the absence of food or psychic stimuli the gastric glands are quiescent. It is chiefly due to the extensive studies of A. J. Carlson on man and lower animals that we now know that this view is incorrect. According to Carlson,[6] a continuous secretion of gastric juice is a normal phenomenon and occurs even in prolonged fasting. The cause is unknown. Presumably it might be due to a persistent secretory tonus in the vagi, the production of secretagogues through the autodigestion of the gastric juice, the endogenous production of histamine-like substances or a combination of these factors.

The studies embodied in this report were made as follows: At 9 p. m. the stomach was emptied and lavaged with an Ewald tube. When the returns were clear, a Levine tube was introduced through the nose into the stomach and continuous suction maintained until 9 a. m. with the Wangensteen apparatus. During this period the patients were shielded from all psychic secretory stimuli, and as a rule sleep was little interfered with. When successfully conducted it is probable that this continuous aspiration more nearly collects the entire gastric output than can be secured by the intermittent evacuation of the stomach. Even so, it is appreciated that varying amounts of gastric juice probably escape into the duodenum. The aspirate is frequently discolored by regurgitated bile and duodenal content. Such specimens should be discarded. From 3 to 10, twelve hour aspirations were carried out on each patient, and in the ulcer cases the studies were repeated after the vagus section.

TABLE 1.—*The Continuous Night Secretion of Gastric Juice in Patients with Carcinoma of the Stomach*

Patient Number	Age	Volume, Cc.	Free Acidity, Clinical Units	Total Acidity, Clinical Units
1	56	260	0	40
2	31	220	21	39
3	74	84	0	44
4	74	75	0	18
5	54	290	8	22
6	60	500	0	25
7	60	200	11	30
8	60	290	0	38
9	30	430	0	41
Average		261	4	33

Table 1 shows the average gastric aspiration obtained from 9 patients with carcinoma of the stomach. The volume varied between 75 and 500 cc., with an average of 261 cc., and the free acidity between 0 and 21 clinical units. Table 2 displays the continuous night secretion in 5 patients with carcinoma of the colon. The volume here averaged 238 cc. and ranged from 85 to 370 cc. The free acidity varied between 0 and 18 clinical units. Table 3 shows the night secretion of 6 patients with chollelithiasis and chronic cholecystitis. The average volume was 385 cc., with a range between 100 and 630 cc. and a free acidity between 0 and 13 clinical units. In considerable contrast to these three groups, table 4 presents the results obtained in 8 patients with duodenal and 2 with gastric ulcers. The average twelve hour continuous secretion for this group was 821 cc., and this decreased to 335 cc. after division of the vagus nerves. The free acidity was 47 clinical units before and fell to 15 units after the operation. In table 5 are presented data from 9 patients with ulcers but with certain complications which make the determination of continuous gastric secretion more uncertain. Four of this group are patients with duodenal ulcer and high grade cicatricial stenosis at the pylorus. Because of the necessity for relieving the obstruction, a subdiaphragmatic section of the vagus nerves was carried out along with a posterior gastrojejunostomy. The material aspirated from the stomach after the operation always contained bile. The remaining 5 patients had stoma ulcers, 3 following gastric resection and 2 following gastroenterostomy. In these also the collection was uncertain because of admixture with duodenal content. However, in spite of this fact a definite reduction in both the volume and the free acidity of the gastric content was brought about by division of the vagus nerves.

TABLE 2.—*The Continuous Night Secretion of Gastric Juice in Patients with Carcinoma of the Colon*

4	58	360	0	15
5	60	170	11	26
Average		238	9	30

These data confirm and amplify those previously reported from this laboratory obtained by similar methods.[7] They provide definite evidence that an abnormally large continuous secretion of acid gastric juice occurs in most patients with ulcer in the absence of stimulation by food or psychic factors. This excessive secretion appears to be due chiefly to an abnormally great secretory tonus in the vagus nerves and is reduced to normal values by complete vagus section.

The Gastric Secretory Response of Ulcer Patients to Histamine Before and After Vagus Section.—It has been demonstrated in experimental animals that histamine stimulates gastric secretion after section and subsequent degeneration of the vagus nerves. It causes secretion of gastric juice from a denervated accessory stomach pouch, and this is not abolished by atropine. The action of histamine must therefore be on the peripheral neuroglandular apparatus or directly on the secreting cells. Studies on the effect of histamine on the human stomach after vagotomy have not been reported.

[7] Dragstedt, Palmer, Schafer and Hodges.[2] Dragstedt and Schafer.[3]

In the present study the response to histamine stimulation was determined by the method of fractional gastric analysis on all the 19 patients in this series before and after section of the vagus nerves. All examinations were made in the morning in the fasting state. A Levine tube was inserted into the stomach and the gastric content aspirated. One tenth cc. of histamine dihydrochloride 1 to 1,000 solution per kilogram of body weight was injected subcutaneously and the stomach emptied every ten minutes for at least one hour. An abundant secretion of acid gastric juice was produced in all patients before operation, and there was *no diminution* either in volume or in free acidity after the vagus section. The response of a typical patient to the injection of histamine before and after vagotomy is shown in table 6.

The Gastric Secretory Response of Ulcer Patients to Caffeine Before and After Section of the Vagus Nerves.—Caffeine elicits a secretion of gastric juice similar in quality to that produced by histamine.[8] This subject has recently been extensively studied by Roth, Ivy and Atkinson.[9] According to these workers, caffeine stimulates gastric secretion in man and the cat but not in the dog. Its effect is not abolished by the administration of atropine. In relatively large doses it produced acute and subacute ulceration of the gastric mucosa in cats. When given to patients with duodenal ulcer it was found to produce a characteristic prolonged secretory stimulation that was considered to have diagnostic value.

The gastric secretory response of the ulcer patients in this study to caffeine was determined by the method of Roth and his associates.[9] After emptying the stomach, 7½ grains (0.5 Gm.) of caffeine with sodium benzoate in 200 cc. of water was instilled through a Levine tube. After thirty minutes the stomach was again emptied, and thereafter ten minute fractional samples were withdrawn for analysis. Tests were made on 17 patients with duodenal, gastric and gastrojejunal ulcers. One patient failed to respond; a second showed a mild stimulation of secretion before the vagus section but not after. The remaining 15 responded with an increase in volume and free acid both before and after the vagotomy. The stimulation was as well defined after the operation as before and in general was less than that produced by histamine. A representative test is indicated in table 7.

The Gastric Secretory Response of Ulcer Patients to Insulin Hypoglycemia Before and After Section of the Vagus Nerves.—Bulatao and Carlson[10] in 1924 discovered that the injection of insulin increases gastric motility. In 1930 Roholm[11] and Kalk and Meyer[12] demonstrated that it also causes a stimulation of gastric secretion which begins when the blood sugar reaches hypoglycemic values. The secretagogue action of insulin can be abolished by the administration of an amount of glucose sufficient to counterbalance the hypoglycemia; furthermore, insulin does not augment gastric secretion in a person with diabetes unless the blood sugar is in the normal range when given The increased secretion of gastric juice in response to insulin is therefore a part of the hypoglycemic syndrome It appears to be due to a stimulation of gastric secretory fibers in the vagi for section of these nerves (Okada [13] and La Barre [14]) or the administration of atropine abolished the effect. For this reason Ihre,[8] Babkin [15] and lately Hollander [16] have recommended the use of insulin hypoglycemia as a method for testing the integrity and secretory function of the vagus nerves to the stomach. Fractional insulin gastric analyses were performed on our patients by withdrawing samples of gastric juice at ten minute intervals following the administration of 20 units of crystalline insulin subcutaneously; all tests were made in the fasting state This test was made on 17 patients before and after vagotomy. Two patients showed no response before vagotomy, so the lack of response following operation was not significant. Fifteen cases reacted to the injection of 20 units of insulin with an increase in the amount and free acidity of the gastric juice. This response was often delayed as long as an hour and was accompanied by a low blood sugar and hypoglycemic symptoms The stimulation of gastric secretion by insulin was not as pronounced as with histamine but approximated that obtained with caffeine. One patient (14, Mr. W. W.) had a slight but definite stimulation of gastric secretion in response to insulin following vagotomy. The remainder of the group were not affected by insulin following vagotomy. Table 8 presents the results in 1 such case.

The Gastric Secretory Response of Ulcer Patients to a Sham Meal Before and After Section of the Vagus Nerves.—The classic researches of Pavlov proved that the sight, smell or taste of palatable food provokes a secretion of gastric juice in the stomach. The effect is a true conditioned reflex and is mediated by the vagus nerves It would appear that the use of this principle in the sham meal ought to be the most effective way to test the excitability of the vagus secretory fibers in ulcer patients as compared with normal persons. Ten of the ulcer patients in this study were given a sham meal gastric analysis before and after vagotomy. The test was performed by having the patient chew certain foods without swallowing The gastric content was aspirated every ten minutes for an hour. Only 3 of the 10 patients showed a definite increase in the volume and acidity of the gastric juice in response to the sham meal before operation. None of the patients responded following the vagotomy. Table 8 presents the findings in 1 case. The unsatisfactory results obtained with this test are probably due to several factors. It is difficult to get patients to chew food and refrain from swallowing some of it. The presence of the indwelling tube doubt-

less exerts a definite psychic inhibition and, lastly, it is probable that more attractive food should have been served.

The Motility of the Empty Stomach of Ulcer Patients Before and After Section of the Vagus Nerves.—The normal stomach in man does not remain inactive in the interdigestive phase but exhibits a periodic activity which gives rise to the hunger sensation. According to Carlson[17] the pressure variations in the stomach as recorded by the usual balloon method are caused by (1) a tonus rhythm, (2) hunger contractions and (3) respiratory and pulse pressure changes. The tonus contractions vary in amplitude but have a remarkable uniformity of rate, twenty seconds. The amplitude increases without a change in rate during hunger periods and is much decreased immediately after a period. The hunger periods are initiated by weak contractions with long pauses; the contractions become stronger, the pauses briefer, with the climax a number of very powerful and rapid contractions approaching incomplete tetanus. Relaxation is relatively abrupt. The periods vary in duration from a few minutes to one and one-half hours, with a quiescence of one-half to two hours between hunger periods.

In a recent review Quigley[18] stated that the majority of workers have found that the hunger contractions of ulcer patients are normal or only slightly exaggerated. Shay and his associates[19] report hyperperistalsis, hypertonicity and hypermotility in uncomplicated duodenal ulcer which coincides with the usual observation of the roentgenologist. Barron and Curtis[20] studied the motility of the empty stomach of a patient with vagotonia and reported that after division of the left or anterior vagus nerve there was a decided decrease in the duration of the periods of motility and in the number and amplitude of the contractions. This effect persisted for at least five months.

In the present studies the balloon for recording gastric contractions was attached to a Miller-Abbott tube, which in turn was connected with a chloroform manometer. The stomach had been emptied for the previous fifteen hours by continuous gastric suction. Seconal 0.9 Gm. by mouth or pentobarbital calcium 0.18 Gm. by rectum was given to encourage sleep during the test. The drugs in these doses were found to have little or no effect on gastric motility and were a great aid in securing satisfactory records.

G. K., a white man aged 42, whose kymographic record is illustrated in figure 1, had a very large gastric ulcer visualized both by x-rays and by gastroscopy. The tracing taken before operation shows gastric motility somewhat more pronounced than usually found in normal man There is a fairly high tonus rhythm culminating in a series of vigorous hunger contractions. Both the tonus and the number and amplitude of the hunger contractions were much reduced by transthoracic section of the vagus nerves.

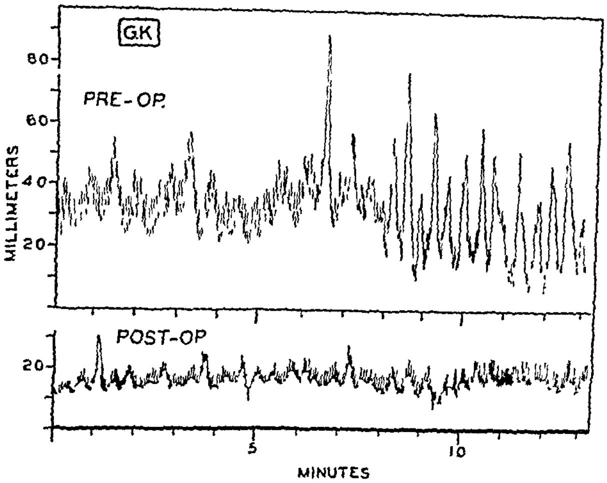

Fig 1 —Representative tracings showing the motility of the empty stomach of a patient with a gastric ulcer before (upper) and after (lower) supradiaphragmatic section of the vagus nerves to the stomach

R V, a white man aged 42, had ulcer symptoms for twenty-three years, and x-rays demonstrated a duodenal ulcer with a crater The tracings in figure 2 show exceptionally vigorous contractions of the empty stomach and almost constant motility before operation, with rather pronounced reduction after section of the vagus nerves

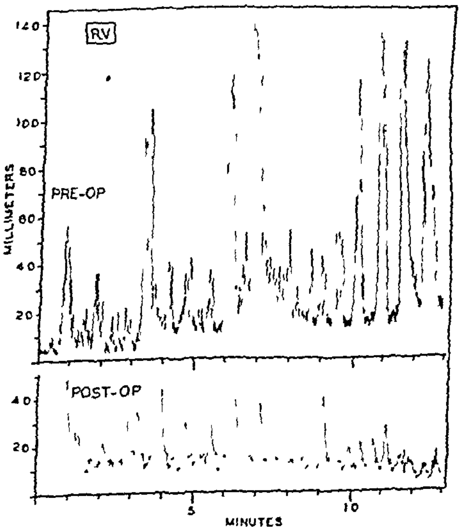

Fig. 2 - Representative tracings showing the motility of the empty stomach of a patient with a duodenal ulcer before (upper) and after (lower) supradiaphragmatic section of the vagus nerves to the stomach

J. P, a white woman aged 54, had ulcer symptoms for eight years with several massive hemorrhages. X-ray examination revealed considerable deformity of the duodenal bulb with high grade obstruction. The tracings in figure 3 show more or less continuous contractions of the empty stomach before operation, with one period of tetany. Because of the pyloric obstruction, a gastroenterostomy was performed and at the same time the vagus nerves were divided in the region of the lower esophagus. The tracings taken after the operation show a rather pronounced decrease in gastric motility. This is, no doubt, in part due to the gastroenterostomy.

In addition to these patients, studies have been made on 2 patients with gastrojejunal ulcers following partial gastrectomy treated by supradiaphragmatic transthoracic vagotomy and on 3 patients with duodenal ulcers. Two of these were treated by simple vagus section above the diaphragm, while on the third a gastroenterostomy was performed for obstruction, and the vagus nerves were sectioned beneath the diaphragm. In each case a definite decrease in the gastric tonus and in the frequency and amplitude of the hunger contractions was produced.

COMMENT

The data obtained in this investigation furnish strong support for the view that an excessive continuous secretion of gastric juice occurs in most patients with gastroduodenal ulcer in the absence of any known type of gastric secretory stimulus. The reduction in this secretion produced by complete division of the vagus nerves to the stomach proves that the hypersecretion is neurogenic in character. It probably represents an excessive secretory tonus in the vagus nerves of central origin and points to some functional disturbance in the nervous system as ultimately responsible for the disease. The presence of excessive motility of the stomach in many ulcer patients and its return toward the normal state after section of the vagus nerves indicates that a hypertonus of the motor augmentor fibers in the gastric vagi is also often present. Both excessive motility and excessive secretion may of course operate to produce an ulcer in the stomach and maintain its chronicity. Of these two factors the experimental data definitely indicate that hypersecretion is the more important. The beneficial results obtained by section of the vagus nerves in ulcer patients do not permit a decision on this point, since both secretion and motility are reduced.

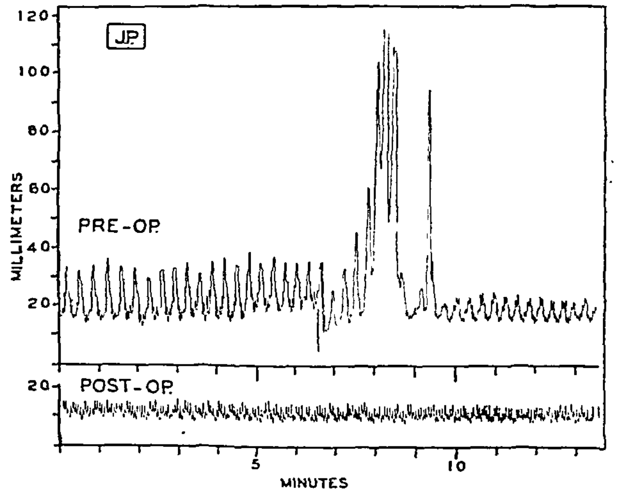

Fig. 3.—Representative tracings showing the motility of the empty stomach of a patient with obstructing duodenal ulcer before (upper) and after (lower) gastroenterostomy and subdiaphragmatic section of the vagus nerves.

While it is perhaps true that the gastric glands of ulcer patients respond to the stimulus of food, alcohol, histamine or caffeine with a greater output of gastric juice or some of its constituents than is the case in normal individuals, the results of this investigation suggest that the most pronounced and regular departure from the normal lies in the volume and acidity of the continuous night secretion. This is apt to be especially large in young patients with duodenal ulcer who present in varying degree other signs of nervous tension and instability. The determination of this night secretion appears to be the most valuable of all the gastric secretory tests from the standpoint of both diagnosis and prognosis. Patients with hypersecretion are especially prone to develop secondary stoma ulcers following gastroenterostomy or gastroduodenostomy or even after partial gastrectomy but respond very favorably to complete section of the vagus nerves.

The persistence of a secretory response to histamine after bilateral vagotomy in man is in harmony with the result obtained on lower animals and indicates that the site of action of histamine is probably directly on the cells of the gastric glands. Caffeine apparently acts at the same point, since stimulation also persists after vagus section. On the other hand, insulin hypoglycemia produces a vigorous secretion of gastric juice through stimulation of gastric secretory fibers in the vagus nerves, and this is completely abolished after bilateral vagotomy. This fact, as Hollander suggests, makes it a very valuable method to determine if the vagus section has been complete. The sham meal has a similar application and deserves further investigation.

CONCLUSIONS

1. The continuous night secretion of gastric juice in the empty stomach of patients with gastric and duodenal ulcers is usually much greater than in normal man.

2. This hypersecretion is chiefly neurogenic in character and is much reduced by section of the vagus nerves to the stomach.

3. The empty stomach of ulcer patients often displays a hypertonicity and hypermotility, with exaggerated hunger contractions, and these are returned toward the normal state after bilateral vagotomy.

4. Complete section of the vagus nerves to the stomach in man abolishes the secretion of gastric juice produced by a sham meal or by insulin hypoglycemia but has little or no effect on the response to histamine or caffeine.

5. The absence of a secretory response to a sham meal or to insulin hypoglycemia is good evidence that section of the vagus nerves to the stomach has been complete.

ABSTRACT OF DISCUSSION

DR. KEITH S. GRIMSON, Durham, N. C.: Dr. Dragstedt and his associates at the University of Chicago have translated the evidence obtained from years of physiologic and clinical study into a surgical interpretation that has developed vagotomy as a valuable addition to the group of operations currently employed for ulcer. Fifteen months ago, after discussions with him, an investigation of the clinical and physiologic effects of transthoracic vagotomy was begun at Duke Hospital. Eighteen patients with refractory ulcers that had produced serious symptoms during an average time of eleven years were subjected to transthoracic vagotomy. The ulcers healed in several weeks and there has as yet been no evidence of recurrence. The physiologic effects produced by vagotomy have been remarkable. Our observations have in most instances agreed with those presented in this paper. Twelve hour night secretion volumes were reduced from an average of 946 cc. before operation to an average of 342 cc. after operation. The acidity of the secretion of the fasting stomach was changed from an average p_H of 1.72 before operation to an average of 3.55 afterward. There was, however, considerable individual variation. Five patients had only moderate reduction. Under the conditions of our experiments both insulin hypoglycemia and histamine produced an increase of free acid before and also after the vagotomy. The increase produced by both was definitely less after operation. The average increase in free acid after histamine before operation was from 29 cc. of tenth normal hydrochloric acid to 64 cc. The average change several weeks and several months after operation was from 7 cc to 18 cc. Insulin hypoglycemia produced an average maximum increase of free acid to 105 cc. before operation and to 23 cc. several weeks and several months afterward. It is not now possible to explain this similar effect of vagotomy on chemical and nervous secretion mechanisms. Gastrometric examination revealed a remarkable reduction to subnormal of the gastric hypermotility observed before operation. The gastric stretch reflex was abolished. Relief of ulcer pain occurred promptly after the vagotomy. This could be related either to reduction of stomach motility, to reduction of acidity or to interference with sensory fibers that might have been present in the vagus. In general we have not been able to disassociate the role played by acidity from the role played by decreased motility in our clinical and physiologic study.

Dr. Francis D. Moore, Boston: Dr. Dragstedt and his group have effectively revived an operative procedure which was given clinical trial several times in the past twenty years with an abdominal approach. These previous experiences with abdominal vagotomy have been generally unsuccessful. The transthoracic operation has many anatomic and physiologic advantages which make it justified to reevaluate entirely the usefulness of vagus division in peptic ulcer. Our work on this subject at the Massachusetts General Hospital has been in progress for about eighteen months and up to the present time we have performed vagus resection on 12 patients suffering from peptic ulcer. The procedure we have used is essentially similar to Dr. Dragstedt's with the one difference that we have opened the diaphragm and resected a portion of each nerve from just below the lung root to the midportion of the gastric fundus. The symptomatic relief experienced by our patients has been much the same as that described by Dr. Dragstedt. The ulceration in our patients has usually healed in one to three weeks, the patients with jejunal ulcers taking somewhat longer to heal. I can corroborate Dr. Dragstedt's secretory findings with but few exceptions. I find that the p_H of gastric contents is raised from 1.0 to 3.0 or more units throughout the day and night and that free acidity is virtually abolished throughout the twenty-four hour period with the exception of isolated observations just before meals or late at night, when 15 to 20 units of free acid may appear. Chloride ion concentration is decreased a variable amount. There is little or no change in total base or in pepsin concentrations. Our studies on motility and sensation have been carried out in collaboration with Dr. William Chapman. We have found motility changes similar to those described by Dr Dragstedt, although there is some return of atypical gastric activity six to eight months postoperatively. In addition we have demonstrated that there is no change in the pain threshold to balloon distention in the lower esophagus, stomach, duodenum or upper jejunum following vagus resection. This signifies that the relief of pain experienced by these patients is not due to regional anesthesia produced by peripheral nerve section. Instead, it results from a fundamental alteration in some aspect of the ulcer-producing mechanism. The ultimate worth of this procedure will rest on the long-term clinical end results. It is too soon to estimate the value of this operation on the basis of data available at present.

Dr. Geza de Takats, Chicago: Dr. Dragstedt and his associates have presented us with the first technically complete vagotomies ever described in man. Partial vagotomies, usually performed below the diaphragm, have been reported many times with promising but not permanent results; nor has any effort been made to prevent regeneration of the vagus nerves. My early vagotomies done in 1936 and 1939 certainly suffered from both of these defects and showed no lasting effect. That it has been clinically possible to reduce both the excessive volume and the acidity of gastric nocturnal secretion by complete vagotomy is the second great advance the authors have made. This reduction of volume and acidity has been definite in my limited experience with the supradiaphragmatic vagotomy. Most striking, however, is the sudden relief of long-lasting epigastric pain, heartburn and hunger pangs. Gastric and esophageal hypertonus and hypermotility are reduced after vagotomy. The motor component in the symptomatology of duodenal ulcer is dominant, even if the acid secretion is the one which initiates and perpetuates the ulcer. This motor activity is not all central; reflex gastric and esophageal spasms originating from the stomach, duodenum, gallbladder, heart or lung have been definitely demonstrated. Vagotomy has a vast inhibiting influence on these reflexes, since it cuts the efferent side of the reflex arc. The pain of the penetrating lesion, deep, boring and continuous, is not mediated by the vagus. Sympathetic block or splanchnic section can stop such pain unless somatic intercostal fibers are involved by peritoneal involvement. I have stopped the pain of a threatening perforation of the duodenum by blocking the left dorsal sympathetics from the sixth to the ninth segment. Vagotomy may have to be combined with typical gastric operations; the abdominal vagotomy has the great advantage of permitting the examination of the local lesion. The immediate problem now is that of case selection; medically resistant young patients with hypermotility, hypersecretion, no serious stenosis or hemorrhage could be selected for vagotomy, while others who have undergone repeated gastric operations, those with marginal ulcers and inflammatory lesions, in whom a subtotal gastrectomy would be indicated, might be given a trial with vagotomy.

Dr. L. L. D. Tuttle, Houston, Texas: Surely the Chicago group has become aware that the present state of affairs for the handling of peptic ulcer is not what it should be. It is only natural after use of such radical procedures as subtotal resection for ulcer that we look for a procedure that may not have such a tendency toward production of a secondary anemia, a picture simulating pernicious anemia: the weakened patient with swollen ankles and one that may fail to hold his weight and strength. J. Shelton Horsley pointed out in 1933, while discovering the neurogenic theory for the causation of peptic ulcer, that if we were to relieve this condition we must control hypersecretion, hypermotility and hypertonicity. Harvey Cushing pointed out that the truest response of the parasympathetic system (the cranial part) came from stimulation of the interbrain or near that point. He lost 3 patients, who at autopsy showed peculiar lesions in the stomach (perforation of the esophagus, the stomach and the duodenum). These were explained on the basis that stimulation of the vagus had caused one or all three of the responses oversecretion, motility and tonus. It may be possible to approach the question from another angle, that of stimulating the sympathetic instead of suppressing the parasympathetic system. In that case one surely would have to adhere to the theory that normal conditions really are an absolute balance between the sympathetic and the parasympathetic. We have been convinced that caffeine has a deleterious effect on the ulcer patient. It is worth knowing that this is a peripheral effect and not central. Our group has made use of the insulin or hypoglycemic state in indicating whether or not we had sectioned all of the vagus. A troublesome feature that we encounter is the delay in emptying time of the stomach—this manifests itself not only in those with slight occlusion of the pyloris but in all of the cases. One we feel sure changed from five hour retention to three hour with the use of belladonna and phenobarbital. All our cases have shown improvement clinically, 1 gaining as much as 42 pounds (19 Kg.) and a second becoming free from troublesome duodenal hemorrhage. Dragstedt points out a way to make use of gastroenterostomy —a procedure that has nearly been discarded. The authors are showing us a good procedure. It may fail to do all that is necessary in every case. With section of the vagus we shall see cases that will lend themselves to gastroenterostomy that otherwise would develop the marginal ulcer.

Dr. A. C. Ivy, Chicago: This contribution is important for at least two reasons. The data indicate that the vagus nerves may be concerned in the etiology of peptic ulcer in man and that the hypercontinuous secretion of gastric juice observed in the majority of patients with an active duodenal ulcer may be affected by vagus section. In addition, the observations increase our knowledge of the effect of the vagi on the stomach of man. A study of the paper suggested that the increased night secretion, which returned toward the normal state after bilateral vagotomy, might be due to the administration of alkalis, which were withdrawn after the operation. It is quite clearly established, in my opinion, that alkaline powders produce what is termed a "rebound secretion" in some patients. Dr. Dragstedt has informed me, however, that most of the patients had not received alkaline powders for several days before the test. The cause of the hypercontinuous secretion which disappeared after vagotomy is of considerable interest from the psychosomatic and physiologic points of view. The fact that the patients did not respond well to sham feeding before vagotomy, even though the meal might have been more attractive, suggests that the appetite mechanism for gastric secretion was not hyperirritable. Several years ago I studied appetite secretion in 6 normal subjects by the use of an indwelling tube. Only 1 responded to the sight of frying and smelling a beefsteak; this subject and 4 others responded to tasting and chewing the beefsteak; and the 6th who did not respond to tasting and chewing, was upset by the process of expectoration. When food is chewed and tasted, two reflex mechanisms for gastric secretion are excited. One is an unconditioned reflex, like the secretion of saliva to acid in the mouth, and the other is a conditioned reflex dependent on learning, which is a reaction to "anticipatory thinking." It would seem that if either of these two mechanisms were hyperirritable in the ulcer patient, more than 3 of the 10 patients would have shown a good response to sham feeding. Necheles and Maskin (*Am. J. Digest. Dis.* **3**:90 [April] 1935) found only a slightly greater secretion in response to sham feeding in 34 ulcer patients as compared to 35 normal subjects. Wolf and Wolff (Human Gastric Function, Oxford University Press) in their subject with a gastrostomy observed increased secretion in the presence of internal conflict, resentment and anxiety even when the subject had no appetite. This indicates that such emotional states do not operate to increase secretion via the appetite mechanism. The response of the authors' patients to insulin before vagotomy was not any greater than that of Ihre's normal human subjects (Ihre: *Acta med. Scandinav.*, supp. 95, 1938). Hence the mechanism on which insulin hypoglycemia operates was apparently not hyperirritable in the author's patients. Unfortunately it is not known on what centers in the brain insulin hypoglycemia acts to stimulate secretion. It may act on some center above the vagal secretory cells in the medulla; for example, on the anxiety mechanism of Wolf and Wolff. The possibility that the hypersecretion is due to a reflex arc the sensory and motor limbs of which reside in the vagi should be considered. This possibility does not require a hyperirritable center at the level of the medulla. Such a reflex mechanism for influencing the motility of the stomach exists in the dog. For example, a duodenal ulcer increases the "tonic motility of the stomach" (type 2 and 3 contractions); this type of motility is abolished by vagus section (Ivy, A. C.: *Arch. Int. Med.* **25**:6 [Jan.] 1920). All of the physiologic vagal mechanisms for gastric secretion can be completely annulled by atropine. The hypernormal interdigestive secretion in peptic ulcer patients cannot be abolished by ordinary doses of atropine. Therefore if this hypersecretion is due to a vagal mechanism it is some abnormal type of vagal effect which is unaffected by atropine unless the factor of the dosage required is concerned. Nevertheless, vagotomy should obviously be more effective than atropine in abolishing the normal or abnormal action of the vagi. Bilateral vagotomy, because it abolishes the cephalic phase of gastric secretion, normal or abnormal, and reduces or abolishes "tonic motility," normal or abnormal, should favor the healing and prevention of recurrences of peptic ulcer. The degree of correctness of this statement depends on whether the stomach of man is like that of the dog and particularly the rabbit, animals which sometimes develop gastric ulcer spontaneously after bilateral vagotomy (Beazell, J. M., and Ivy, A. C.: *Arch. Path.* **22**:213 [Aug.] 1936. Meek, W. J., and Herrin, R. C., *Am. J. Physiol.* **109**:221 [Aug.] 1934).

Dr. Lester R. Dragstedt, Chicago: I wish to express my sincere appreciation to the men who have taken part in this discussion and who have thereby contributed so much to the problem under consideration. It is especially pleasing that our observations have been so largely confirmed. I should like to emphasize the point that these findings are in harmony with the concept that gastroduodenal ulcer is a psychosomatic disease. Presumably the tensions and strains of modern life produce aberrant activity in the central nervous system and this, in turn, leads to abnormally great secretory and motor tonus in the vagus nerves. An increased secretion of gastric juice in the empty stomach becomes then the objective evidence of this central nervous system disturbance which is at the basis of ulcer disease. These facts provide a challenge to the students of psychoanalysis to employ the technics of their discipline in the treatment of patients with duodenal ulcer guided by the effects of their procedures on gastric secretion, which is subject to quantitative measurement. The clinical results of vagus section in patients with gastroduodenal ulcer have thus far been so satisfactory and the physiologic concepts back of the operation so appealing that I feel even at this early date (the oldest patient was operated on not quite three years ago) warranted in recommending transthoracic section of the vagus nerves as a substitute for subtotal gastrectomy in the treatment of duodenal, gastrojejunal and proved gastric ulcers. When definite obstructive symptoms are present the operation should be combined with gastrojejunostomy or gastroduodenostomy, and in this case the division of the vagus nerves may be done beneath the diaphragm.

TREATMENT OF SCARLET FEVER

LIEUTENANT COMMANDER PAUL ASHLEY (MC), U.S.N.R.

Two hundred and ninety-eight consecutive patients with scarlet fever admitted to this activity during June and July 1945 were observed for (1) the degree of toxemia on admission, (2) the type of streptococcus present in the throat, (3) the response to various methods of treatment and (4) the incidence and types of complications. The patients were grouped according to treatment methods, and comparable groups were made up of alternately admitted patients. All patients were free from complications when admitted, and the rash had been present less than thirty-six hours. All convalescent serum used in these cases was made from blood drawn from convalescent scarlet fever patients on the eighteenth day of the illness.

METHOD OF STUDY

Grouping of Cases and Treatment Used.—Groups A1 and A2: A comparison of convalescent serum and antistreptococcus (horse) serum.

Fifty of the first 99 patients were given 50 cc. of human convalescent scarlet fever serum intravenously on admission (group A1), and 49 were given 10 cc. of antistreptococcus serum (commercial, New York State Health Department) intravenously on admission (group A2). As nearly as possible alternate admissions were selected for each group, but men (5 out of 54 tested) found sensitive by skin test to the antistreptococcus serum were not subjected to desensitization but were assigned to the convalescent serum group.

Groups B1 and B2: A comparison of convalescent serums secured at separated intervals in the epidemic.

Forty-nine of the second 99 patients were given, on admission, 50 cc. of human convalescent scarlet fever serum intravenously which had been prepared six weeks

---

This article has been released for publication by the Division of Publications of the Bureau of Medicine and Surgery of the U. S. Navy. The opinions and views set forth in this article are those of the writer and are not to be considered as reflecting the policies of the Navy Department.

or more previously (group B1), and 50 patients were given, on admission, 50 cc. of human convalescent scarlet fever serum which had been prepared within the previous week from patients who were about to go to duty. The serum used in group B1 was drawn from a group of convalescent scarlet fever patients from whose throats the percentages of streptococci listed in table 1 were cultured. This serum is hereafter referred to as "old" serum.

TABLE 1.—*Sources of Old Serum*

	Type of Group A Streptococci		
	3	17	19 + ANCT*
Present in this percentage of patients	2.	37	36

* This abbreviation designates those group A streptococci which are "not common types."

TABLE 2.—*Sources of New Serum*

	Type of Group A Streptococci		
	3	17	19 + ANCT
Present in this percentage of patients	11.6	36.6	50

The serum used in group B2 was drawn from a group of convalescent scarlet fever patients from whose throats the percentages of streptococci listed in table 2 were cultured. This serum is hereafter referred to as "new" serum.

Groups C1 and C2: A comparison of convalescent serum with and without penicillin as additional treatment.

Fifty of the third series of 100 patients were given 50 cc. of pooled human convalescent scarlet fever serum intravenously on admission (group C1), and 50 were given 50 cc. of *pooled human convalescent scarlet fever* serum intravenously on admission, penicillin 30,000 units on admission and penicillin 15,000 units every *three hours until the temperature* had been normal for five consecutive days (group C2). It had appeared from previous observations that patients receiving penicillin *on admission* had a smoother course than some apparently less ill who had received only convalescent serum.

TABLE 3.—*Method of Grading*

1 Temperature		2 White blood cell count	
98.6 to 99 F. ..	Grade 1	Below 10,000 .	Grade 1
99 to 101 F.....	Grade 2	*10,000 to 15,000*..	Grade 2
101 to 103 F.	Grade 3	15,000 to 20,000	Grade 3
103 F. and above .	Grade 4	*Above 20,000*	Grade 4
3 *Rash.*		4 Pharyngitis and tonsillitis	
Slight	Grade 1	Slight	*Grade 1*
Moderate	Grade 2	Moderate..	Grade 2
Moderate to intense	Grade 3	Moderate to severe	Grade 3
Intense (with petechiae)..	Grade 4	Severe with edema and exudate	Grade 4
5. Toxic signs:			
One sign	Grade 1		
Two signs.........	Grade 2		
Three signs..	*Grade 3*		
Four or more signs	Grade 4		

GRADING OF TOXEMIA

When each patient was admitted, his (1) temperature and (2) white blood cell count were taken, the (3) rash and (4) pharyngitis and tonsillitis were graded by the admitting medical officer and (5) systemic toxic signs such as nausea, vomiting, *epistaxis,* headache, enlarged cervical lymph nodes, fainting and malaise were noted. Each of these five findings was graded on the arbitrary basis shown in table 3. The grading of numbers 3 and 4 was determined by one medical officer in over 250 of the 298 cases and therefore was *relatively uniform.*

The toxemia of each patient was numerically evaluated *by* averaging the grades of these findings and, in turn, the toxemia of the groups of cases was numerically evaluated by averaging the grades of the component cases.

DETERMINATION OF STREPTOCOCCUS TYPE

At the time of admission and before any treatment was *given, throat cultures* were taken on blood agar plates. Subsequent isolation and typing were done by the local epidemiology unit. The typing serums available *were those for types 3, 17 and 19* of group A *plus* the usual grouping serums. Cultures of beta-hemolytic streptococci which were group A but not types 3, 17 or 19 *are classified as group A,* not a common type, or ANCT. There were a few cultures in each group of cases which could not be grouped or typed. They are classified as "positive but no type."

TABLE 4.—*Toxemia on Admission*

Group	A1	A2	B1	B2	C1	C2
Toxemia grade	2.03	1.89	1.8	2.0	1.8	2.1
Relation of comparable groups	A1 7% more toxic than A2		B2 11% more toxic than B1		C2 16.6% more toxic than C1	
Maximum toxemia = 4.0						

TABLE 5.—*Determination of Streptococcus Types*

Throat cultures: Group	A1*	A2*	B1	B2	C1	C2
Type 3.....	3	4	7	9	6	6
Type 17...	11	12	1.	10	9	11
Type 19..	0	0	8	10	15	12
ANCT.....	18	12	6	4	6	5
19 + ANCT ..	18	12	14	14	21	17
Positive no type	5	4	5	3	9	5
Group G. ..	..			1	.	.
Negative.	11	15	10	15	2	4
No culture	2	2			3	4

* *At the time these groups were observed the type 19 serum was faulty and it is believed by the epidemiology unit that at least 50 per cent of the cultures called ANCT were really type 19*

RESPONSE TO TREATMENT

The response to treatment in groups A1, A2, B1, B2 and C1 was estimated on temperature *and* the necessity *for* the use of penicillin. If a patient's temperature dropped to 99 F. or below during the first seventy-two hours and stayed at 99 F. or below forty-eight hours or more, and if his *condition* had not necessitated administration of penicillin during the first seventy-two hours, he was *considered* as having responded well to the treatment. If the temperature persisted above 99 F. for more than seventy-two hours or if *his condition necessitated* the administration of penicillin during *the first* seventy-two hours, he was considered as having responded poorly to the treatment.

In group C2 the response to treatment was estimated on the temperature and the necessity for the *administration of penicillin* longer than ten days. If a patient's temperature dropped to 99 F. or below during the first seventy-two hours, and *if* his *condition did not* necessitate the use of penicillin in unusual amounts or for more than ten days (to satisfy the policy of giving penicillin until the temperature had been *normal* for five days), he was considered as having responded well to the treatment. If a patient's temperature persisted above 99 F.

for more than seventy-two hours or more than a standard amount of penicillin was needed. he was considered as having responded poorly to the treatment.

Any systemic reactions to the convalescent serum or antistreptococcus serum in groups A1 and A2 were noted in order to compare untoward effects of the two substances.

COMPLICATIONS DEFINED

The following were considered complications:

Fever above 99 F. for a consecutive period of forty-eight hours or over for which no cause could be found and which appeared after the temperature had dropped below 99 F. and remained below 99 F. for forty-eight hours or more.

Pharyngitis or tonsilitis which appeared within the first five days of the disease but after the temperature had been 99 F. or below for forty-eight hours.

Cervical adenitis which became accentuated after the patient had initially responded well to treatment.

Lower respiratory infections such as pneumonia, bronchitis and pleurisy.

Otitis media, acute, with or without drainage.

Sinusitis, acute, which could be identified to the satisfaction of the medical officer by a sufficient number of the following signs and symptoms: nasal obstruction and/or drainage, fever, pain in one or more sinuses, tenderness on pressure or percussion over one or more sinuses, orbital cellulitis, or erysipelas of the face associated with other signs of sinus infection.

Rheumatic fever which could be conclusively diagnosed by adequate combinations of major and minor symptoms.

Table 6.—*Group A Streptococci and Type Percentages*

Group	A1	A2	B1	B2	C1	C2
Total cases	32	28	34	33	36	37

Group	A1	A2	B1	B2	C1	C2
Patients	50	49	49	50	50	50
Good response	27	36	36	19	30	40
Poor response	23	13	13	31	20	10
Toxemia grade	2.03	1.89	1.8	2.0	1.8	2.1

Patients who developed pharyngitis or tonsillitis after the fifth day and who had responded well to the initial treatment were considered to have become cross infected.

RESULTS

The total number of patients harboring group A streptococci in each group and the type percentages were as shown in table 6.

Group C2 patients responded better to the treatment than any other group and considerably better than the comparable group C1. It should also be noted that group C2 patients were 16⅔ per cent more toxic than those in group C1. In view of this toxicity the better response of group C2 to the treatment assumes greater meaning. Although a comparison of the treatment response in group C2 to that in any other group except C1 is not quite accurate, it does seem significant that though the toxemic grade for C2 was higher than any other group the response to treatment was consistently better.

The response to treatment is roughly proportional to the grade of toxemia on admission in all groups except C2.

There were three reactions to the administration of the convalescent serum in group A1, and all were of mild degree. There were thirteen reactions to the administrations of the antistreptococcus serum, and five of these were severe, with further elevation of an already high temperature.

Table 8.—*Complications*

Group	A1	A2	B1	B2	C1	C2	Total	% of Total
Patients	50	49	49	50	50	50	298	
Fever only	3	5	..	5	5	1	19	6.3
Pharyngitis and tonsillitis	1	2	..	1	..	..	4	1.3
Cervical adenitis	4	1	2	2	2	..	11	3.6
Lower respiratory infections	5	3	1	1	1	..	11	3.6
Otitis media, acute	1	3	1	1	2	1	9	3.0
Sinusitis, acute (orbital cellulitis and erysipelas)	9	1	5	5	2	2	24	8.0
Rheumatic fever	1	..	4	4	1	1	11	3.7
Total complications	24	15	13	19	13	5	89	29.5
Percentages having complications	48	30.6	26	40	26	10	29.7	
Cross infections	4	1	1	0	1	1		
Toxemia grade	2.03	1.89	1.8	2.0	1.8	2.1		

The relative incidence of complications is in proportion to the toxemia on admission in all groups except C2.

CORRELATION OF TYPE INCIDENCES IN CONVALESCENT SERUM AND RESULTS OF TREATMENT

The sources of the two serums used in groups B1 and B2 had the type incidences in the total number of patients having group A streptococci as noted in tables 1 and 2, and groups B1 and B2 themselves had the type incidences in the total number having group A streptococci shown in table 9.

The incidence of type 3 beta-hemolytic streptococci in the source group for the old serum was slightly (2.4 per cent) greater than it was in the group B1 patients who received it. The incidence of type 3 beta-hemolytic streptococci in the source group for the new serum was much (15.4 per cent) less than it was in the group B2 patients who received it. The incidence of type 19 ANCT in the source group for the new serum was moderately (10 per cent) greater than it was in the group B2 patients who received it. There was no appreciable difference in the incidence of type 17 in the source groups for the old and the new serum and in the group B1 and B2 cases. There was also no appreciable difference in the incidence of type 19 + ANCT in the source group for the old serum and the group B1 cases.

Table 9.—*Type Incidences in Groups B1 and B2*

	Source of Old Serum	B1	Source of New Serum	B2
Total group A streptococci	338	34	60	36
Type 3	25%	20.6%	11.6%	27%
Type 17	37%	39%	36.6%	33%
Type 19 + ANCT	36%	40.4%	50%	40%

Table 10.—*Recovery of Beta-Hemolytic Streptococci*

	Group B1			Group B2		
	Type 3	Type 17	Type 19 + ANCT	Type 3	Type 17	Type 19 + ANCT
Total cases	7	13	14	9	19	13
Cases giving poor response	1	5	3	8	7	5
Cases giving complications	0	5	3	1	3	6

Table 10 shows the number of times each type of group A beta-hemolytic streptococci was recovered from groups B1 and B2 and the cases of each type which gave poor response to treatment and those which presented complications.

It is noteworthy that in the patients harboring type 3 streptococci the convalescent serum called new was much less effective in evoking a good treatment response than was the convalescent serum called old. Table 9 gives the incidence of type 3 streptococci in the source of the new serum. There are no other trends indicating type specificity of the convalescent serum in these results.

No correlation between the type of streptococci recovered from the throats of these patients and the occurrence of complication can be demonstrated in a study of individual records.

COMMENT

It would be highly desirable to use convalescent scarlet fever serum of known antibody titer. Until practical methods of determining this titer are developed, care should be taken that the source of the serum is bacteriologically similar to the group of patients receiving it.

During an epidemic or endemic of scarlet fever, repeated determination of the predominant types of streptococci present is important so that the therapeutic susceptibility of these organisms can be estimated once or twice each week.

It is dangerous and absurd to use the sulfonamide drugs for patients infected with sulfonamide resistant organisms, since numerous severe reactions have been observed leading to prolonged morbidity and occasionally permanent damage to the patient. Fever and toxic signs from administration of sulfonamide drugs frequently cloud the clinical picture and make evaluation of the course of the disease difficult. Furthermore, rashes from sulfonamide drugs (and other "innocuous" preparations such as A. P. C. Tabs) are frequently confused with scarlet fever during an epidemic. This makes prolonged and at times injurious observation necessary by the contagious disease section of a hospital in order to prevent errors in diagnosis and grouping of patients.

In general the patients seen during June and July 1945 had a milder form of the disease than those seen at the height of the epidemic in March and April 1945.

SUMMARY

The degree of toxemia of scarlet fever varies greatly; therefore the toxemic state of the patient is not an indication for or against the diagnosis.

Fifty to 60 per cent of the cases of scarlet fever seen here during June and July 1945 were caused by group A beta-hemolytic streptococci types 3, 17 and 19. Since these types were persistently sulfonamide resistant in laboratory tests, the use of sulfadiazine in treatment of these patients was contraindicated.

The response to treatment of scarlet fever with convalescent scarlet fever serum alone was roughly proportional to the degree of toxemia on admission and was not satisfactory.

The response to treatment of scarlet fever with convalescent scarlet fever serum plus penicillin is much better than that with convalescent serum alone or antistreptococcus serum alone, regardless of the severity of the illness as interpreted by the numerical evaluation of the toxemia. The response to the treatment of scarlet fever with antistreptococcus serum was better than that with convalescent serum in this study, but when the difference in the calculated toxemia of the groups is considered the difference in response assumes less significance. In view of the work of Rothbard (to be published) concerning the higher titer of antibodies in convalescent serum drawn on the thirty-fifth day, it would be valuable to compare the antistreptococcus serum with convalescent serum drawn at the later date. The response to the treatment of scarlet fever with convalescent serum alone is better when the streptococcus type incidence in the source group for the convalescent serum is similar to that of the group treated. Immediate reactions to the intravenous administration of antistreptococcus serum (derived from horses) was much more frequent than immediate reactions to the intravenous administration of convalescent serum. The incidence of complications in scarlet fever treated with convalescent serum alone or antistreptococcus serum alone was roughly proportional to the toxemia on admission.

The incidence of complications in scarlet fever treated with antistreptococcus serum alone was considerably less than that with convalescent serum alone, but when the difference in toxemia of the groups is considered this difference in complications assumes less significance. The incidence of complications in scarlet fever treated with convalescent serum plus penicillin was much less than that in patients treated with convalescent serum or antistreptococcus serum alone, regardless of the toxemia on admission.

A study of individual records in this series indicates that the incidence of rheumatic fever as a complication of scarlet fever has no relation to the toxemia on admission or the type of organism present in the throat during the initial stages of the scarlet fever. There was no correlation between the complications and the type of streptococcus present in the throat during the initial stages of the scarlet fever.

CONCLUSION

Human convalescent scarlet fever serum intravenously administered 50 cc. or more (depending on the toxemia) within twenty-four hours of the appearance of the rash, together with penicillin 30,000 units intramuscularly on admission and 15,000 units every three hours until the temperature has been normal for five days, is the treatment of choice for scarlet fever indicated by this study.

American Animal Psychology.—Perhaps the most impressive contribution of the early postwar period of World War I was the great fund of evidence derived through research on the developmental aspects of behavior and the genesis of behavior patterns. This trend toward a dynamic theory of animal personality led not only to searching out the nature of ontogenetic behavior changes in many animals from the early embryonic stages but also to special investigations of "native" factors in behavior. This work has continued in many laboratories, with real progress toward clarifying the problems of adaptive behavior. Unfortunately in recent years, with increasing emphasis on the intensive investigation of adult behavior patterns, there has been a swing away from interest in the genesis of individual behavior. There is however an underlying tendency in American animal psychology to give ontogeny its due, and it may well be that a resurgence of this important factor in the earlier development of the field will account for important postwar metamorphoses. Perhaps through such changes in the coming years animal psychology may at length graduate to the status of "comparative psychology."—Schneirla, T. C.: Ant Learning as a Problem in Comparative Psychology, in Twentieth Century Psychology, New York, Philosophical Library, 1946.

AN UNUSUAL LICHENOID DERMATOSIS

CAPTAIN LAWRENCE C. GOLDBERG
Medical Corps, Army of the United States

Never before in the history of dermatology have there been so many people affected with lichenoid lesions as there have been in the South Pacific Theater of War and other allied areas. Hundreds of individuals have been returned to the Zone of Interior with this cutaneous disorder and hundreds still remain there. Those who have seen the disease both in that area and in the United States are immediately struck with the fact that, though many of the lesions are typical of hypertrophic lichen planus, in many respects the disease is entirely different from any type heretofore described. Despite the doubts in the mind of some as to the common basis of the lesions, there is no question (fig. 1) that the distribution of many of these lesions are the same. They affect the mucous membranes in the same way and are associated with the same identical pruritus, but they appear to be less orderly and of a wider nature. Clinically, as well as geographically, these lesions are exotic.

This unusual dermatosis presents itself in three different phases. So variable are its clinical manifestations that numerous and varied diagnoses are suggested both early and late.

(*a*) *Dermatitis Phase* (fig. 2).—The patient, as a rule, states that at first areas of erythema with small pruritic pustules have been seen on the dorsum of the feet, hands, forearms and legs. These remain for varying periods of time and are often treated with some type of lotion or salve. Following this initial state, one or two things happens: Either discrete verrucous and papulosquamous lesions or an exfoliating dermatitis develops.

(*b*) *Exfoliating Dermatitis Phase.*—The patients seen in this phase are extremely ill, usually having low grade to definite fever, loss of appetite and pronounced loss in weight. The skin is scaling and weeping from the top of the head to the bottom of the feet; the lymph glands are greatly enlarged and a foul odor is present. (I have never seen any of these patients die, but death has occurred, and on admission to this hospital several have been placed on the seriously ill list.)

(*c*) *Lichenoid Phase.*—It is at this time that the lichenoid lesions similar to hypertrophic lichen planus arise, and these can be seen on almost any part of the body, though certain areas are more severely affected than others. The lesions are very prominent on the flexor surfaces of the arms, the inner aspects of the thighs, the buttocks and the dorsum of the hands and feet. The type of lesion is for the most part similar to the hypertrophic type of lichen planus rather than to the polygonal umbilicated papulosquamous lesions so aptly described by Erasmus Wilson almost a century ago. I have never seen a classic lichen planus papule with Wickham's striae in an original case. Such a lesion has been seen, however, in 3 relapsing patients, all of whom had been in this country six months or more after returning from the Pacific areas and India. The lesions are a deep purple red, which in many instances deepens as treatment progresses Again differing from the usual lichen planus, this disease more conspicuously affects the face, especially the eyelids and ears. As it subsides the definite erythema ab igne appearance of the eyelids is seen. This becomes so striking that after one has seen a number of cases the diagnosis of lichenoid dermatitis is immediately suggested on seeing the patient's eyelids. The axillary, pubic and perianal areas are often involved and commonly weep, thus leading to secondary infection, with resulting confusion in diagnosis. The elbows and knees are similarly affected, so that oftentimes a casual glance could easily lead to the diagnosis of psoriasis vulgaris. Later the lesions become either pigmented or depigmented, depending on the reaction of the individual. The deeply pigmented lesions which appear on the face, arms and legs are strongly suggestive of a grouped pigmented syphiloderm (figs. 3 and 4) and have so been called. Again the pigmentation may be so generalized and the lesions so verrucoid that the possibility of Darier's disease, urticaria pigmentosum, and even acanthosis nigricans has been suggested. Some of the lesions assume polycyclic and orbicular forms on the body and extremities and to the uninitiated look like tinea corporis. The depigmented areas may coalesce and strange and bizarre appearances result (fig. 5).

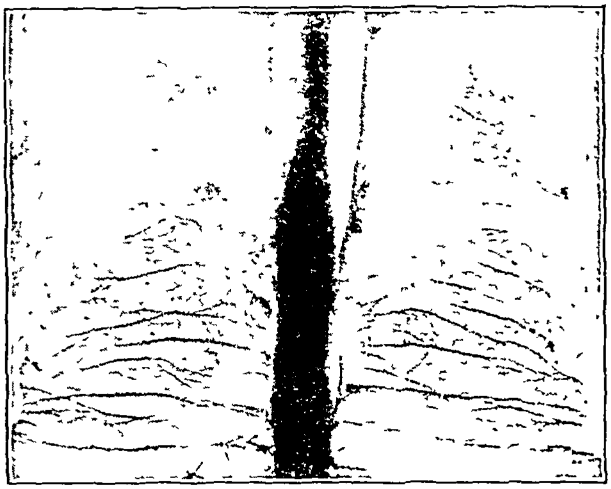

Fig. 1.—Lichenoid lesions involving the wrists

The mucous membranes of the mouth (fig. 6), lips, penis and vulva are definitely affected, and lesions have been present in these areas in 12 of the 60 cases. Since the eruption was so wild in its nature, it seemed likely that proctoscopy[1] and gastroscopy might reveal further involvement. A large number of these cases were examined, and the most striking lichen planus lesions that I have ever seen on the mucous membranes were present on the rectum in 3 of the 20 cases so studied to date. These occurred on the columns of Morgagni but never in the crypts. They were usually 1 cm. or more above the anocutaneous junction but never in the sigmoid colon. A typical description of these lesions was presented as follows:

> External examination. The perianal region is covered with confluent and discrete lesions which are consistent with lichen planus There is a chronic anal ulcer in the posterior commissure There is no evidence of fistula, external hemorrhoids or pilonidal sinus.
>
> Digital: Sphincter tone is normal. The prostate is normal in size and shape. The rectal mucous membrane is smooth.

From the Oliver General Hospital, Augusta, Ga

Pfc John H MacDonald photographed the patients

Col Hew B McMurdo M C, commanding officer, Oliver General Hospital, and Col Arthur N. Ferguson M C, chief of medical service, cooperated in making this study possible

[1] The proctoscopies and gastroscopies were done by Major Jack S. Goltman, M C, A. U S

Anoscopic: There are no internal hemorrhoids. The rectal columns on the anterior and lateral walls show a grayish white mucosal alteration which has the appearance of an artificially appliqued material. This does not wipe off or bleed when swabbed with an applicator. The lesion begins at the pectinate line and extends along the column, but not into the crypts, for a depth of 1.5 cm.

Proctoscopy: Long instrument passed full length. There are no lesions above the terminal rectum. Vascular markings are distinct.

To date no lesions have been found in the stomach by gastroscopy. Reexamination of some of these patients showed complete clearing of the lesions following treatment.

Occasional cases were associated with alopecia and, because of pyogenic infection of the scalp, presented a varied and sometimes bizarre appearance. The palms and soles (figs. 7 and 8) were frequently involved; over 75 per cent of the cases showed lesions of the nails. One of the most typical findings was the scaling débris beneath the terminal end of the nails, which was often so thick that they were raised from their beds. There were also numerous pitted and lusterless areas of the nails similar to and at times indistinguishable from those often seen in psoriasis vulgaris. Occasionally subungual raindrop pigmentation was seen. In the more severe cases one half to two thirds of the nail was destroyed or had become so brittle that it could be easily removed.

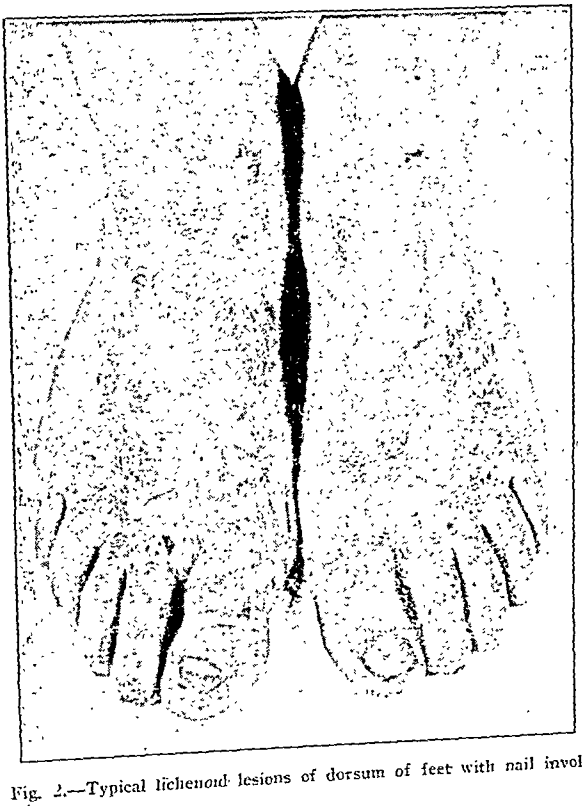

Fig. 2.—Typical lichenoid lesions of dorsum of feet with nail involvement.

ETIOLOGY

The most interesting question that immediately suggests itself is Why is this disease so common in the South Pacific and climatically similar areas but so uncommon in the other theaters of war? The same kind of people are fighting and the war is just as intense in the Euorpean theater as in the Pacific. Sir Graham Little[2] stated that MacCormack, in charge of a large base hospital for skin diseases in World War I, found lichen planus extremely rare and not increased in the military or civilian population. He did state, however, that prior to the war he had seen numerous instances of the disease following scratch marks and wounds. The latter statement is pertinent, as will be seen, to a consideration of some of the cases in the South Pacific. In a report covering over 2,000 dermatologic cases among soldiers in World War I, Guy[3] found only 1 instance of lichen planus.

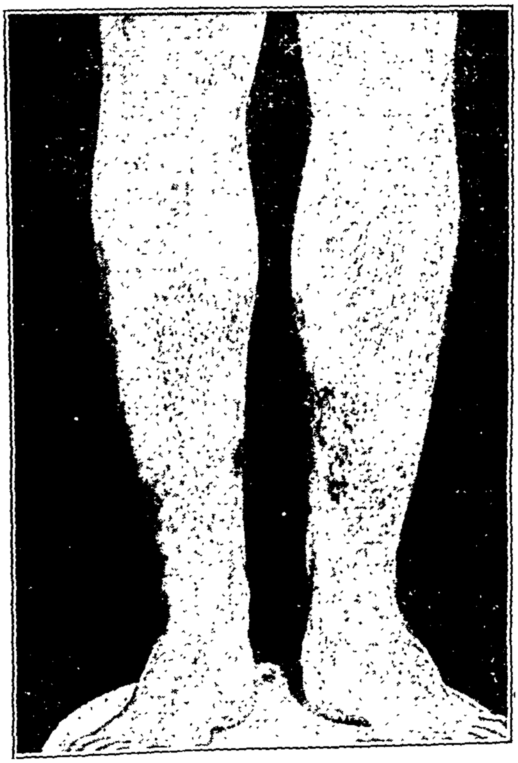

Fig. 3.—Grouped pigmented lesions resembling a grouped pigmented syphiloderm.

The question of drug idiosyncrasy arises, and one must consider atabrine, used by hundreds of thousands in the Pacific Theater of War as well as in other areas. It has been shown by observers that atabrine is capable of producing skin reactions, as in the interesting reports by Noogin and Calloway,[4] Nayudu[5] and Storey.[6] In none of these patients were lichen planus-like lesions found, but severe exfoliating dermatitis was described. Lichenoid lesions such as those described earlier in this paper, have been known to occur in drug eruptions caused by arsenic, bismuth and bromides, so that the thought that atabrine might cause this unusual dermatosis is not improbable. I have been unable to reproduce these lesions, however, in the cases observed and treated by suppressive or intensive therapy with atabrine. All these were maintained on suppressive atabrine therapy while they were being treated, and in no instance did any new lesions appear while under observation. It is true, however, that some of the hypertrophic lesions would weep, but this could readily have been a reaction to local treatment even though it was mild, because the skins of many of these patients were extremely sensitive. Several patients developed their first attacks of malaria or relapsed while in this hospital and were treated with intensive atabrine therapy, but there was no aggravation of their skin lesions. One patient in particular, with severe exfoliating dermatitis plus his lichenoid lesions, has been observed for eight months, during which time he has been receiving continuous suppressive atabrine therapy; he has recovered except for scattered sepia brown pigmentation. Patch and intradermal tests with atabrine were done in a few of these patients and all were found to be negative. No passive transfer tests were made.

[6] Storey, W. E.: Toxic Exanthema Following Prolonged Atabrine Administration and Resembling Brill's Typhus Fever: Report of Case, J. M. A. Georgia 27:317 (Aug.) 1938.

Two patients developed severe otitis media and 1 a virulent Vincent's infection of the throat with definite flare-up of the skin lesions after sulfonamide therapy. This suggests to some extent a pyogenic or allergic background. Although atabrine may be a definite causal factor or an agent that prepares the soil, more evidence will have to be uncovered before it can be pinned down as the exclusive and certain etiologic factor. It is quite possible that even if atabrine is a cause of this cutaneous disorder the classical geographic sites such as New Guinea and Burma and similar areas may provide other necessary factors. It may be of value to examine a large number of natives in typical geographic areas where lichenoid lesions have been found to be prevalent and note whether they have or have had similar eruptions. Future study will undoubtedly answer the question whether this is true sensitivity to the drug or a toxic effect related to the amount ingested.

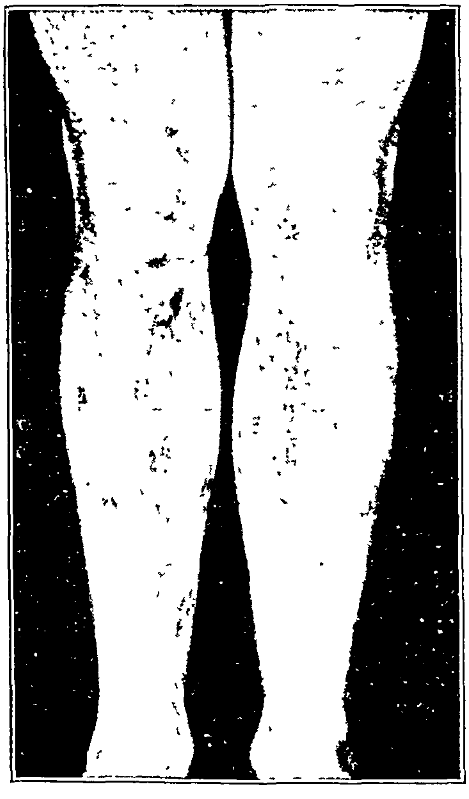

Fig. 4.—Grouped pigmented lesions resembling a grouped pigmented syphiloderm.

Malnutrition must also be considered as a possible etiologic factor. The only patients that showed loss of weight and poor general health were those in the exfoliating phase, a nonspecific effect. It was striking that practically all the patients in the lichenoid phase of the disease were well nourished. Nevertheless the fact that they were not receiving fresh vegetables and were on rationed diets may be significant.

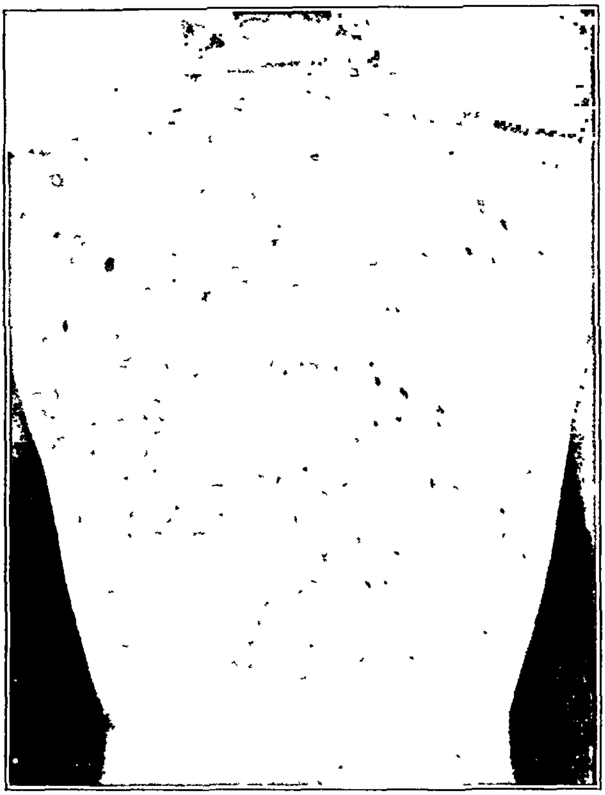

Fig. 5.—Typical depigmented lesions.

Since the eruption is common on the face and dorsum of the hands, the possibility of light sensitivity should be considered, particularly in view of the relation between light sensitization and infection. To some extent the pigmentation of the skin caused by atabrine may even protect individuals from the sunlight—an interesting possibility deserving further study.

The reported small incidence of lichen planus in World War I would at first glance tend to minimize an emotional or neurophysiovascular mechanism as the cause of this unusual dermatosis. All types of people have been affected: combat soldiers, general staff officers, doctors, nurses, Wacs and soldiers doing routine tasks in no way associated with active combat duty. Many of these cases were from New Guinea, Biak and Morotai, where there had been beach landings, invasions and heavy battle casualties. When one considers that this environment is totally different from that ever experienced by the military personnel transported here, away from their conditoned civilization and in stations where the sexes have been isolated from each other, the possible emotional etiology appears more significant. The nature of the weather, its rain and constant humidity, the mud, the jungle with its "routine diet" of trees and underbrush and its almost total isolation from the rest of the world increasingly suggest a large emotional factor. Virtually every patient affected with this dermatosis as seen here had severe hyperhidrosis of the palms and soles—a disturbance long known to be associated with neurophysiovascular imbalance. Some of those affected by this eruption are said to have anhidrosis at the start of their disease, but this symptom has as yet not been observed here. In addition, there is the added factor of infection caused by scratches, infected bites, wounds, ulcerations, the ever present miliaria with its pruritus and impetiginization, and countless other emotionally disruptive factors. As the soldiers say, "practically every one has jungle rot in New Guinea."

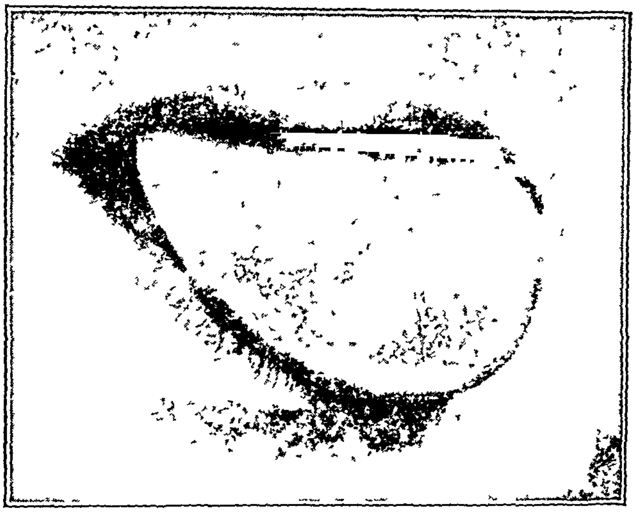

Fig 6—Lichen planus like lesions of the tongue which disappeared after four injections of 0 02 Gm of oxophenarsine hydrochloride

MINUTE STRUCTURE

Biopsies of several lesions were examined microscopically and in general showed the changes similar to those often seen in lichen planus. One interesting finding was an increased pigmentation in the corium in the pigmented type of lichen planus. In 1 instance a lymph gland from such a case was examined and pigmented granules were seen throughout the stroma.

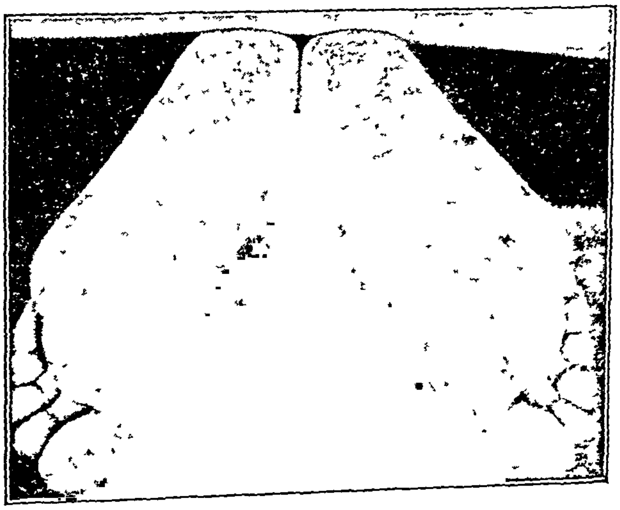

Fig 7.—Lichenoid lesions of the heels

LABORATORY DATA

Routine laboratory studies revealed no specific findings. There were occasional increases in the eosinophils, but this is not uncommon in patients returning from the Pacific. None of the patients showed blood findings that were compatible with hemopoietic change, and in the few cases that were examined for hepatic pathologic change none was found. No false biologic reactions were noted. Sedimentation rates by the Wintrobe method were elevated in 70 per cent of the patients with eczematous lesions and in all of the exfoliating cases.

TREATMENT OF THIS DERMATITIS

The treatment of this eruption will vary according to the phase of the disease.

(*a*) *Treatment of Dermatitis Phase.*—Since I treated all these cases in the Zone of the Interior, the dermatitis phase offered no great problem because of its infrequency. The skin of these patients, it was seen, was extremely sensitive, so that even the mildest substances were irritative. For this reason treatment had to be individualized. The salves and lotions used were in all instances very mild and when applied were covered with bandages which were not removed for twenty-four hours unless unfavorable reactions had occurred.

(*b*) *Treatment of Exfoliating Phase.*—In general the exfoliating cases were treated by the usual methods employed in any exfoliating dermatitis.

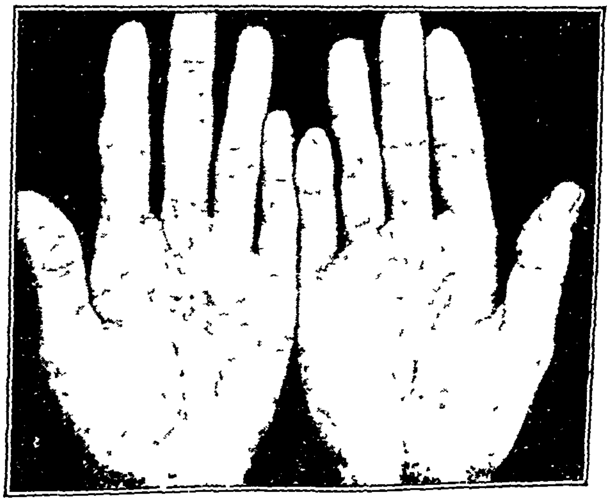

Fig 8—Lichenoid lesions of the palms

1. Continuous local wet dressings were used. Potassium permanganate in 1:5,000 dilution was the drug of choice The dressings were applied over the entire body if necessary; they were then covered with towels which were fastened with safety pins This form of therapy was usually continued day and night until the oozing, weeping and secondary infection had been controlled.
2. Sulfonamides were never used.
3. High caloric diets were given with added vitamin medication. Crude liver extracts in 2 to 5 cc doses were given intramuscularly either every day or every other day as indicated Amino acids were given orally in large amounts.
4. Colloid baths were made up of cornstarch and baking soda if and when the patient was ambulatory.

During this exfoliative phase no specific treatment was administered.

(*c*) *Treatment for the Lichenoid Phase.*—Arsenic in various forms has been used in the treatment of lichen planus for many years. Because of its occasional successes a system of treatment was developed employing an arsenical. Oxophenarsine hydrochloride (Mapharsen) was given in small doses, 0.02 Gm. biweekly. To date 60 patients have been so treated,[7] and in some the results have been excellent (figs. 9 and 10), with involution even after four injections. Most of the patients showed improvement with decreased pruritus between the first and the third injections. The mucous membrane lesions shared in this response, and in 1 case (fig. 6) with a large plaque on the dorsum of the tongue the lesion disappeared after the fourth injection of oxophenarsine hydrochloride.

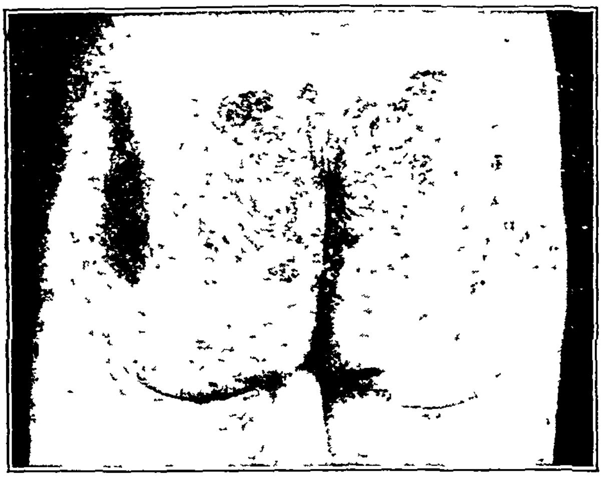

Fig. 9.—Lichenoid lesions of the buttocks of five months' duration.

Although this treatment is admittedly empirical, the encouraging results warrant its future use in the treatment of true lichen planus as well. If successful, such effects as we have seen in our group of cases would be a far cry from the day when White[8] stated that "cure seems to depend largely on natural evolution."

Several of these patients treated with oxophenarsine hydrochloride developed fever ranging from 99.8 to 102 F. about six hours after the first injection, and for this reason the drug had to be discontinued. Although none of these patients had shown any clinical or laboratory evidence of hepatic damage on admission, it was felt that they had a subthreshold hepatitis which was activated by these small doses of oxophenarsine hydrochloride and which might well have been caused by atabrine. Their icterus indexes were definitely raised, and some developed clinical jaundice as evidenced by scleral changes. These reactions subsided in forty-eight to seventy-two hours, during which time the patients suffered nausea and vomiting. This was relieved by the administration of 1,000 cc. of 10 per cent glucose intravenously and the generous use of amino acids by oral administration. Although it appeared that these patients took longer to get well than those who tolerated the oxophenarsine hydrochloride this was a warning that the drug should be used cautiously and discretely, if at all, in treating patients with "exotic lichen planus."

Previous to hospitalization here, many of these patients had received penicillin in large amounts, both intramuscularly and locally, without benefit, except to control secondary infection. Many also had received sulfonamides, both internally and locally, with no real gain and even with occasional harm.

COMMENT AND SUMMARY

This paper deals with a large number of cases of an unusual lichenoid and exfoliating eruption returned because of this disease, to the Zone of the Interior from the South Pacific Theater of Operations and geographically similar areas. The distribution and character of the lesions usually indicated the correct diagnosis. The most common single finding was a hypertrophic erythematopapulosquamous lesion with a tendency toward confluence. At no time was a classic lichen planus papule seen in an early case. The eruption was "exotic" in character and commonly involved areas not usually affected in true lichen planus: i. e. the scalp, eyelids, face, palms, soles and nails. The mucous membranes, genitalia and anal areas were involved in 20 per cent of the cases. Proctoscopy has revealed in 10 per cent of the cases examined appliqued lesions on the columns of Morgagni but not in the crypts. To date gastroscopy has not demonstrated any lesions. Many of the patients responded well to 0.02 Gm. of oxophenarsine hydrochloride given biweekly. These improvements occurred between the first and third injections; in no case were more than ten injections necessary to bring about involution of the lesions.

The pigmentation resulting from the eruption remained for long periods of time. Depigmented types of lesions were unchanged by treatment. Mucous membrane lesions responded promptly, and in 1 case a large plaque on the tongue cleared after four injections of 0.02 Gm. of oxophenarsine hydrochloride. Several of the patients treated with oxophenarsine hydrochloride developed fever, nausea and vomiting about six hours after the first injection of 0.02 Gm., suggesting the association of hepatic damage in these patients easily exacerbated by this drug and very likely first caused by atabrine. Oxophenarsine hydrochloride should be used with great discretion, if it is used, in treating patients with this eruption.

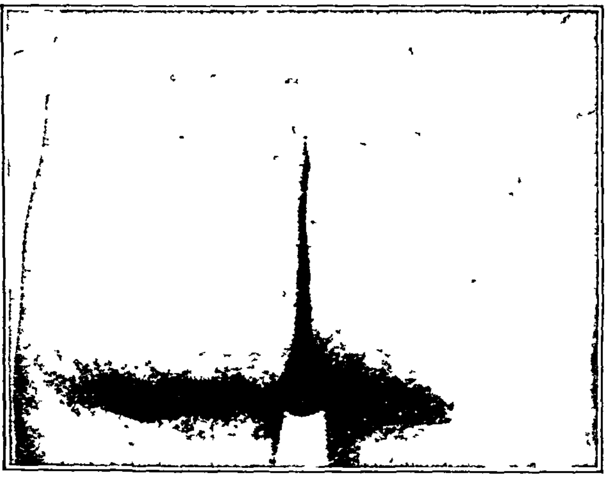

Fig. 10.—Same case as in figure 9 after four injections of 0.02 Gm. of oxophenarsine hydrochloride and ten days after therapy.

Patch and intradermal tests with atabrine when done were found to be negative. No passive transfer tests were made. No false biologic reactions were noted, and in none of the cases in this series were changes in the hemopoietic system found. Sedimentation rates by the Wintrobe method were elevated in 70 per cent of the patients with eczematous lesions and in all the exfoliating cases.

---

[7] Since this paper was written, in February 1945, 63 more of these cases have been seen. Of the total of 123 cases, 1 came from North Africa, 4 from India and the remainder from central and northern New Guinea. More recently several soldiers returned from India were found to be afflicted with this unusual dermatosis. *In all those from* India, atabrine had been stopped at the first symptom of the eruption, but it appeared to have progressed nevertheless along with symptoms of pruritus. Twelve of the total of 123 patients were Negroes.

[8] White, C. J.: Lichen Planus, J. Cutan. Dis. 37:671 (Oct.) 1919.

Although the principal purpose of this paper is to describe the unusual features of this perplexing dermatitis, the problem of its etiology excites the interest. Atabrine must be strongly considered, although it caused no exacerbations of the skin lesions when used here as suppressive or intensive therapy for malaria in patients with this disease. The neurophysiovascular mechanism, photosensitivity and infection appear to play roles, as may as yet unknown geographic factors. Notable undernourishment appeared only in the exfoliating cases, which of course is not specific for this disease. Nevertheless, large doses of multivitamin tablets and amino acids were administered in all cases. No definite conclusions could be drawn as to a possible nutritional factor in producing this dermatosis.

EFFECT OF SYNTHETIC LACTOBACILLUS CASEI FACTOR IN TREATMENT OF SPRUE

WILLIAM J. DARBY, M.D., Ph.D., EDGAR JONES, M.D.
and
HOWARD C. JOHNSON, M.D.
Nashville, Tenn.

In recent years the view that no essential differences exist between tropical and nontropical sprue has become acceptable. Hanes[1] has emphasized this point and has further pointed out the relative frequency of reported instances of this disease from the entire United States and from northern Europe. He reports 66 cases of sprue encountered in the Duke University Hospital during a period of eight years. One hundred and fifty-eight cases of pernicious anemia were admitted during this same period, giving a ratio of 1 patient with sprue to 2.5 cases of pernicious anemia.

The fundamental defect in sprue appears to be impaired absorption of various substances from the gastrointestinal tract, whereby a deficiency of a number of factors may be brought about. Various micro-organisms suspected as causal agents in the past have been excluded as playing an etiologic role. The work of Castle, Rhoads and their associates[2] in Puerto Rico did much to evolve concepts of the pathogenesis of sprue. The resemblance of several features of this disease to those seen in pernicious anemia had long been noted. These authors showed that sprue occurred both in patients with and in patients without intrinsic factor in their gastric juice. In the group with intrinsic factor the sprue syndrome was brought about, presumably, by insufficient dietary or extrinsic factor. Analysis of the Puerto Rican diet indicated that a deficiency in extrinsic factor was probably of common occurrence. This is in accord with the occasional observation of response of a patient with sprue to a full diet. The similarity to pernicious anemia was further indicated by the demonstration that the liver of a patient dying of untreated sprue contained no erythrocyte maturating factor. Furthermore, in those patients with sprue who were anemic the bone marrow characteristically showed the megaloblastic arrest typical of that seen in pernicious anemia in relapse. Finally, the glossitis of sprue and the glossitis of pernicious anemia are indistinguishable.

Liver extract effective in the treatment of pernicious anemia has been found to be effective in the treatment of sprue, although the response in the latter disease is often less complete and more liver extract may be required for a given response than in pernicious anemia.[1] Indeed, Hanes[1] found 4 of his 66 cases of sprue to be refractory to even very large doses of liver extract administered parenterally.

Criteria generally accepted for the diagnosis of sprue are glossitis, diarrhea with increased fat in the stools, loss of weight, pigmentation of the skin, macrocytic anemia, moderate leukopenia, impairment of absorption as indicated by a flat oral glucose tolerance curve and vitamin A tolerance curve, a very low serum carotene and a characteristic gastrointestinal pattern on x-ray examination. As mentioned previously, some of these findings may be lacking.

Effective treatment of sprue with liver extract and improved dietary results in improvement in the majority of symptoms and findings. The glossitis is relieved within a few days, and evidence of papillary regeneration is noted a day or so later. The diarrhea usually ceases within a week. Flatulence and other gastrointestinal symptoms are usually controlled promptly. Hematologic improvement is rapid. Glucose tolerance curves become more nearly normal within a few weeks. The changes in vitamin A absorption and in serum carotene values following treatment occur slowly, if at all. Weight gain is rapid and is associated with an almost insatiable demand for food.

There has been described a deficiency syndrome in the monkey which is characterized by anemia, leukopenia, diarrhea, oral lesions, facial edema, weight loss and death.[3] The organic factor(s) required by the monkey to prevent this deficiency disease was differentiated from nicotinic acid, riboflavin and thiamine and was named vitamin M.[4] Vitamin M was found in crude liver extracts and in yeast. Further studies have shown that this essential factor is different from a large group of well recognized members of the vitamin B complex including pantothenic acid, choline, para-aminobenzoic acid, pyridoxine and inositol.[5] Day and his co-workers[6] have recently demonstrated that vitamin M deficient monkeys respond to the intramuscular administration of small quantities of a highly purified Lactobacillus casei factor. It is of interest

that doses of certain purified liver extracts which were effective in the treatment of pernicious anemia were not effective in the prevention of the nutritional cytopenia in the monkey. Finally, vitamin M deficiency developed in monkeys fed the Goldberger blacktongue producing diet,[7] a diet on which Miller and Rhoads[8] found that pigs lost intrinsic factor from gastric juice and maturating factor from the liver.

The association of diarrhea and dysentery in the monkey with this deficiency has frequently been commented on.[9] The various similarities of vitamin M deficiency in the monkey to the sprue syndrome in man has led us to test the efficacy of the newly synthesized L. casei factor[10] in the treatment of 3 cases of this disease. The rapid clinical and hematologic responses which have followed the administration of this pure synthetic material have been briefly reported elsewhere in preliminary notes.[11] It is our purpose in the present communication[12] to describe these cases in detail and to present additional data obtained during the period of several weeks of observation of these patients. It appears that the response to this single factor has been as complete as is ordinarily experienced following the use of liver extract.

The patients whose courses are described here were maintained throughout their hospital stay on regular ward diets but devoid of organ meats. Patient 3 received no meat products in any form during his hospital course. The crystalline L. casei factor was prepared for injection by dissolving it in distilled water (15 mg. in 3 cc.) by the addition of a minimal quantity of disodium phosphate, and this solution was autoclaved at 10 pounds pressure for fifteen minutes. Fresh solutions were prepared at three day intervals.

The vitamin B complex excretion studies reported were determinations of thiamine (thiachrome procedure), riboflavin (fluorometric method) and N-methylnicotinamide excretion in the urine for a two hour period following oral doses of 5 mg. of thiamine, 5 mg. of riboflavin and 50 mg. of nicotinamide. The vitamin A tolerances were run following a standard oral dose of 200,000 international units of vitamin A.

REPORT OF CASES

CASE 1.—*History.*—A white man aged 51 entered Vanderbilt University Hospital on Sept. 24, 1945 with complaints of sore mouth, diarrhea, weakness and loss of weight over a period of ten months. This had begun rather suddenly, and disability had been progressive. He had lost about 28 pounds (12.7 Kg.) soon after the onset of his complaints; in the four weeks prior to admission he had lost an additional 10 pounds (4.5 Kg.). He had passed five to seven loose stools daily, most of these during the night. The stools were described as white or light yellow. No foul odor had been noted from them. He had observed gradually deepening brown pigmentation of exposed areas of his skin. Blisters had initiated the complaint of sore mouth early in his illness. These had disappeared shortly, leaving him with a diffusely sore tongue. His appetite had been poor throughout his illness, but there had been apparently little, if any, qualitative changes in his diet. For six weeks prior to admission he had taken 2 quarts of milk and 6 eggs daily. Much flatulence and belching had occurred during his illness. Slight swelling of the legs and feet had been noted occasionally. The past history revealed nothing relevant. He had had good health until the onset of his present illness.

Physical Examination.—The patient was emaciated and weighed 107 pounds (48.5 Kg.). The mucous membranes were pale. The skin of the face, neck, hands and feet was deep brown. No pigmentation was observed on any mucous surfaces. The tongue was diffusely red, smooth and glistening (fig. 1). No lymph node enlargement was noted. The chest was barrel shaped and moved poorly. Inconstant squeaks were heard over the lung fields, mostly at the bases. The heart showed nothing of note. The blood pressure was 90/50. Nothing abnormal was noted on examination of the abdomen. The liver and spleen were not felt. There was slight pitting edema of the ankles. The knee and ankle jerks were normally active, and there was no impairment of the vibratory sense.

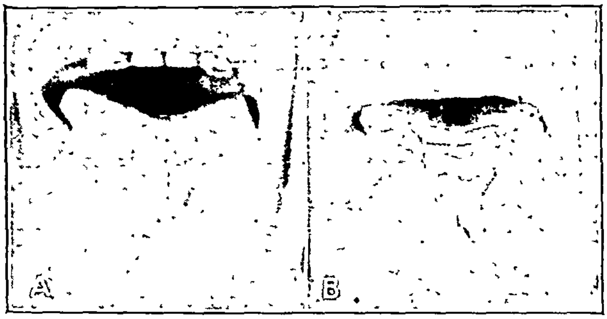

Fig. 1 (case 1).—Appearance of tongue (A) before treatment; (B) three weeks after first treatment. Papillary regeneration of about this extent had been apparent approximately two weeks earlier.

Laboratory Examination.—The urine was negative for albumin and sugar on two occasions, with specific gravities of 1.013 and 1.018 respectively. Nothing of significance was found in the sediment. The urine was not tested for urobilinogen. Values for red and white blood cells, reticulocytes, packed cell volume and hemoglobin are given in figure 2. Differential count of the white blood cells showed 59 per cent segmented neutrophils, 2 per cent juveniles, 35 per cent lymphocytes and 4 per cent monocytes. No increased segmentation of the neutrophils was noted. The red blood cells generally appeared large and showed considerable variation in size and shape. Platelets appeared slightly reduced in number on the smear. Gastric analysis showed 10 degrees of free hydrochloric acid after administration of 50 cc. of 7 per cent ethyl alcohol. The serum icterus index was 6. Total serum proteins were 5.21 Gm. per hundred cubic centimeters, with 3.36 Gm. of albumin. The serum calcium was 8.8 mg. per hundred cubic centimeters. Serum phosphorus was 3.7 mg. per hundred cubic centimeters. An uptake of 5.5 per cent radioactive ferrous iron was found with a dose given one day after treatment was begun. The stools were light yellow to brown and were not foamy or foul smelling. When rubbed between the fingers they had the consistency of cold cream. No parasites or ova were found. The guaiac test was negative for blood. On staining with sudan III three stool specimens were said to show no increased amount of fat. Chemical analysis on two occasions showed fat to comprise 37 per cent and 44 per cent of the dry weight of the stools respectively. The total nitrogen content of two twenty-four hour stool specimens was 3.91 Gm. and 4.89 Gm. respectively. Results of oral glucose tolerance tests, before and after treatment, are given in figure 3. The vitamin A tolerance curve showed a fasting level of 95 international units per hundred cubic centimeters, at five hours 127 international units and at nine hours 117 international units.

[12] A vast literature has accumulated on the hemopoietic activity in chicks and in rats treated with sulfonamide drugs of a number of compounds which have been variously termed B_c, B_c-conjugate, L. casei factors (of which there are at least three), "folic acid," factors U and R, and the like. It is not our purpose in this paper to review the interrelationships of these factors. For recent summaries of the problem the reader is referred to the following reviews: Wieder, S.: The Present Status of Lactobacillus Casei Factor, Pearl River, Lederle Laboratories, Inc., June, 1944. Fig. 2 (case 1).—Hematologic responses. Each upright bar represents the intramuscular injection of 15 mg. of synthetic L. casei factor. Weight changes are shown at top.

Corresponding values for serum carotene ranged from 18 to 21 micrograms per hundred cubic centimeters. B complex excretion tests gave two hour excretion values of thiamine 0.02 mg., riboflavin 0.58 mg. and N-methylnicotinamide 2.54 mg. Intravenous glucose tolerance tests using 20 Gm. of glucose gave the following values: fasting, 90 mg. per hundred cubic centimeters; five minutes, 194 mg. per hundred cubic centimeters; fifteen minutes, 144 mg. per hundred cubic centimeters; thirty minutes, 84 mg. per hundred cubic centimeters; one hour, 58 mg. per hundred cubic centimeters, and one and one-half hours, 75 mg. per hundred cubic centimeters. X-ray examination of the gastrointestinal tract showed the typical atony of the small intestine with pooling of the barium. An electrocardiogram showed low voltage and isoelectric T waves, interpreted as indicating myocardial disease.

Course.—Beginning on October 4 he was given 15 mg. of synthetic L. casei factor daily for eighteen days by intramuscular injection. Four days after treatment was begun his tongue was no longer sore; the next day evidence of papillary regeneration was present. The hematologic response is given in figure 2. The diarrhea had subsided by eight days after the beginning of treatment. At about this time he developed considerable edema of his feet and legs. This gradually disappeared in four or five days. The blood pressure was 110/74 on the eleventh day of treatment. The pigmentation of the skin gradually decreased. His appetite became excessive and the weight gain was rapid (fig. 2). He appeared quite vigorous and by three months after beginning treatment he had gained 43 pounds (19.5 Kg.).

Serum proteins three weeks after the institution of therapy had increased to a total of 6.77 Gm. per hundred cubic centimeters, with 4.35 Gm. of albumin per hundred cubic centimeters. A stool specimen examined two months after treatment was begun showed 29 per cent of dry weight to be fat. At this same time 137 international units of vitamin A was found in the blood serum; no carotene was present. A second gastrointestinal x-ray examination twelve days after treatment was begun showed no change from that observed before therapy was instituted.

Case 2.—*History.*—A white woman aged 22 entered Vanderbilt University Hospital on Oct. 15, 1945 complaining chiefly of diarrhea of three months' duration. Five to six stools were passed daily. These were bulky and foul smelling. The color of the stools had varied greatly during her illness. Cramping abdominal pain had occurred usually with each bowel movement. Six weeks after the onset of diarrhea she delivered a full term infant. After delivery she vomited one to two times daily for two weeks and began to lose weight rapidly. The diarrhea persisted until admission to the hospital. She lost from 20 to 25 pounds (9 to 11 Kg.) below her usual nonpregnant weight during this three month period. Weakness had been progressive during this time. She was brought to the hospital by ambulance, being unable to stand. Since her marriage eighteen months before her diet had consisted of jam, hominy and sweet potatoes for breakfast, beans, cabbage and hominy for lunch and beans, cabbage, hominy and occasionally vegetable soup for dinner. Her appetite had become increasingly poor, so that during her pregnancy only small amounts of these foods were eaten. For five weeks prior to admission she had been given by her local physician biweekly injections of considerable amounts of thiamine, niacin, pantothenic acid, riboflavin and pyridoxine without benefit.

Six weeks before admission it was noted that the skin of her arms was darker than normal. She had not been exposed to sunlight. Her tongue became sore three weeks before admission. Her legs had tingled throughout her illness.

Physical Examination.—The patient was small and emaciated and appeared chronically ill. She weighed 64 pounds (29 Kg.). Her skin exhibited dark brown diffuse pigmentation over the hands, wrists and feet. The scleras were faintly icteric. The buccal mucosa was pale. The gums were soft and bled readily. The tongue was pale, with much atrophy of the papillae and areas of redness along the margin. The thyroid was not enlarged. The lungs were clear on physical examination. The heart was not enlarged. A blowing systolic murmur of moderate intensity was heard over the entire precordium. The blood pressure was 95/58. The abdomen was scaphoid. There was no tenderness. The liver and spleen were not palpable. The extremities were quite thin. There was no edema. The knee and ankle jerks were active, and vibratory sense was not impaired.

Laboratory Examination.—At the time of admission the urine showed a trace of albumin and of sugar as the only findings of note. It later became entirely normal. It was not tested for urobilinogen.

The majority of the hematologic findings are shown in figure 4. Differential count of the white blood cells showed 54 per cent segmented neutrophils, 3 per cent stabs, 0.5 per cent eosinophils, 40 per cent lymphocytes, 2 per cent monocytes and 0.5 per cent neutrophilic myelocytes. The red blood cells appeared well stained and generally large, with moderate variation in size and shape. The platelets appeared to be slightly reduced in number on the stained smear. The platelet count was 200,000 per cubic millimeter by an indirect method. Bone marrow obtained by sternal aspiration before treatment showed generalized hyperplasia with many megaloblasts. The serum icterus index was 12. Total serum proteins were 5.59 Gm. per hundred cubic centimeters, with 4.02 Gm. of albumin. The serum calcium was 10.9 mg. per hundred cubic centimeters, the serum phosphorus 4 8 mg. per hundred cubic centimeters. Gastric analysis revealed free hydrochloric acid after injection of histamine. Three and five-tenths per cent of a dose of radioactive ferrous iron was taken up. This dose was given on the day of the first injection of "folic acid."

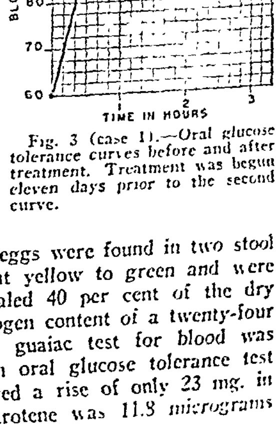

Fig. 3 (case 1).—Oral glucose tolerance curves before and after treatment. Treatment was begun eleven days prior to the second curve.

A small number of hookworm eggs were found in two stool specimens. The stools were light yellow to green and were greasy to touch. Analysis revealed 40 per cent of the dry weight to be fat. The total nitrogen content of a twenty-four hour stool was 2.90 Gm. The guaiac test for blood was negative on three occasions. An oral glucose tolerance test performed before treatment showed a rise of only 23 mg. in a three hour period. Serum carotene was 11.8 micrograms, per hundred cubic centimeters, serum vitamin A 90 international units, serum vitamin C 0.0 mg. per hundred cubic centimeters. The vitamin A tolerance curve following administration of 200,000 international units of vitamin A was 60 international units fasting, 118 international units at three hours, 686 international units at five hours and 671 international units at nine hours. Serum carotene ranged from 17 to 22 micrograms per hundred cubic centimeters. The vitamin B complex excretion test showed values as follows: thiamine 0.03 mg., riboflavin 0.06 mg. and N-methylnicotinamide 4.84 mg.

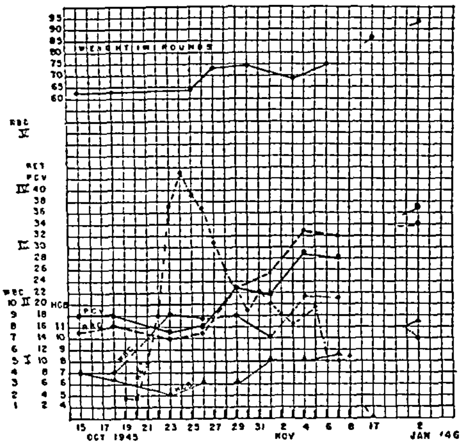

Fig. 4 (case 2).—Hematologic responses. Each upright bar represents the intramuscular injection of 15 mg. of synthetic L. casei factor. Weight changes are shown at top.

Course.—Beginning on October 19 the patient was given 15 mg. of synthetic L. casei factor daily by intramuscular injection for nineteen days. Four days after treatment was begun the soreness of her tongue had disappeared. Papillary regeneration followed rapidly. The hematologic response is shown in figure 4. By the twelfth day of treatment the diarrhea had ceased. There was rapid gain of strength, appetite and weight. After five days of therapy mild generalized edema developed; this lasted a few days and then disappeared. Twenty-nine days after the onset of treatment she weighed 86½ pounds (39 Kg.), a gain of 22½ pounds (10 Kg.) over her admission weight. After five days of treatment the bone marrow showed a predominance of normoblasts; this finding persisted six days later. There was a progressive increase in platelets with treatment until after seven days they had reached a level of approximately 2,000,000 per cubic millimeter (indirect method). They remained at about this level during the next twelve days of observation.

When seen seventy-five days after the first injection of "folic acid" she appeared vigorous and had no complaints. Her weight at this time was 94 pounds (43 Kg.), a gain of 30 pounds (14 Kg.) since the time of admission to the hospital. However, she was found to have a moderate macrocytic anemia at this time. All pigmentation of the skin had disappeared.

Case 3.—*History.*—A white man aged 67 entered Vanderbilt University Hospital on Nov. 8, 1945 complaining of weakness and diarrhea over a period of several years. He had been admitted to the hospital in 1939, at which time a diagnosis of sprue had been made. All of the findings typical of this disease were present then. He was treated with large doses of liver extract, with a resulting reticulocyte peak of less than 6 per cent when his initial erythrocyte count was 2.62 million per cubic millimeter. There was a gradual increase in red blood cells and hemoglobin, but these never reached a satisfactory level. It was observed that he developed considerable edema of his feet and legs after treatment with liver extract was begun. Six and one-half weeks after this first admission he was readmitted because of increasing anemia, although he had been receiving 100 units of liver extract weekly. On the second admission he responded slowly to treatment with liver extract and transfusions. Between 1939 and the present admission he had received liver extract irregularly, noting, however, that he felt much better when getting it. He had had occasional bouts of diarrhea lasting as long as several weeks. Weight loss had accompanied each bout of diarrhea. His tongue had been sore at intervals. Swelling of his legs occurred intermittently. He had drunk considerable whisky over a period of years but none recently because it burned his mouth and throat. For some time before the present admission he had noted increasing pigmentation of his hands and wrists.

His appetite had remained good. His diet was low in meat and vegetables, however. It consisted mostly of milk (1 quart daily), 2 eggs daily, cereals, syrup, jelly, bread and butter.

Physical Examination.—The patient appeared chronically ill. The skin was somewhat loose, and there was dark brown pigmentation of the hands, forearms, face, neck and ankles. There was slight pallor of the skin and mucous membranes. The scleras did not appear icteric. The tongue was red about the tip, and there was some papillary atrophy along the lateral margins near the tip. Several bright red spots were seen on the soft palate. Small epitrochlear, cervical, axillary and inguinal nodes were palpable. The chest moved poorly and was generally hyperresonant. The breath sounds were heard poorly. The heart was small and quiet. The blood pressure was 110/70. The abdomen was slightly full about the umbilicus. There was no tenderness. The liver and spleen were not felt. There was a hydrocele of the left tunica vaginalis and atrophy of the right testicle. There was no edema of the ankles. The knee and ankle jerks were sluggish. Vibratory sense was diminished over both legs.

Laboratory Examination.—A casual specimen of the urine, which had a specific gravity of 1.028, showed no abnormal constituents. The majority of the hematologic findings are given in figure 5. Differential count of the white blood cells showed 50 per cent segmented neutrophils, 1.5 per cent eosinophils, 3 per cent basophils, 44 per cent lymphocytes and 1.5 per cent monocytes. A slightly increased segmentation of the segmented neutrophils was noted. The red blood cells appeared to be well stained, were predominantly macrocytic and showed moderate variation in size and shape. The bone marrow showed hyperplasia, with many megaloblasts and erythroblasts. Platelets as counted by an indirect method ranged around 200,000 per cubic millimeter. The serum icterus index was 3. Serum calcium was 9.7 mg. per hundred cubic centimeters, and serum phosphorus 3.5 mg. Total serum proteins were 5.98 Gm. per hundred cubic centimeters, with 3.79 Gm. of albumin. Gastric analysis revealed free hydrochloric acid without alcohol or histamine stimulation.

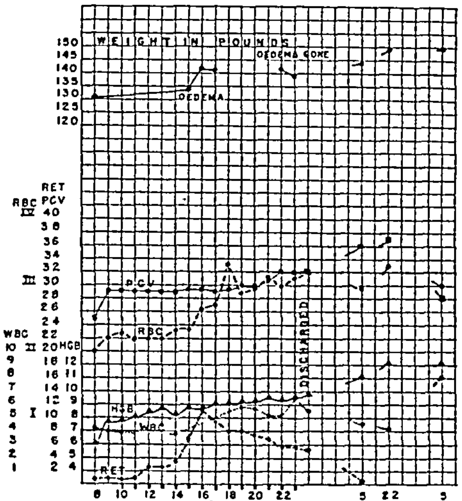

Fig. 5 (case 3).—Hematologic responses. Each upright bar represents the intramuscular injection of 15 mg. of synthetic L. casei factor. Starting on November 25, 5 mg. of this material was given daily by mouth.

Two per cent of a dose of radioactive ferrous iron was taken up, this being given on the day of admission. The stools were chalky white in appearance. No ova or parasites were found. The guaiac test for blood was negative. Analysis of the stool showed a fat content of 23 per cent dry weight. Total nitrogen of a twenty-four hour stool was 4.11 Gm. Values for oral glucose tolerance curves are given in figure 6. The vitamin A tolerance curve after administration of 200,000 international units of vitamin A showed 119 international units fasting, 127 international units in three hours and 169 international units in five hours. The serum carotene ranged from 18 to 21 micrograms per hundred cubic centimeters. Values shown by vitamin B complex excretion tests were thiamine 0.04 mg., riboflavin 0.32 mg. and N-methylnicotinamide 4.49 mg.

X-ray examination of the gastrointestinal tract showed puddling of barium in the small intestine characteristic of that seen in sprue and other deficiency syndromes.

Course.—Beginning on November 10 the patient was given eighteen injections of 15 mg. of synthetic L. casei factor intramuscularly in a period of fifteen days. He was then given 5 mg. of this material by mouth daily, which he has continued. Soreness of his tongue disappeared after four days of treatment. Papillary regeneration was apparent a few days later. Much edema of his feet and legs was noted on the seventh day of therapy. This subsided in a few days. Ten days after treatment was begun the bone marrow showed normoblasts as the predominant young red blood cells. On the eleventh day of treatment a second vitamin A tolerance curve gave values of 101 international units fasting, 114 international units at three hours, 129 international units at five hours and 133 international units at nine hours. The carotene level ranged from 21 to 25 micrograms per hundred cubic centimeters.

A second x-ray examination of his gastrointestinal tract with a barium meal was made thirteen days after treatment was begun. This showed no change from the earlier findings.

There was a rapid gain in weight, amounting to 8 pounds (3.6 Kg.) during his hospital stay of fourteen days after treatment was begun. When seen forty-two days after his first treatment he had no complaints and appeared vigorous. At this time he had gained 17 pounds (7.7 Kg.) above his hospital admission weight. Serum vitamin A on this date was 89 international units, serum carotene 13 micrograms per hundred cubic centimeters. He said that all oral and substernal soreness had gone and that he could now drink whisky without any sensation of burning.

COMMENT

The pattern of response exhibited by these 3 patients with sprue has been similar, and it resembles in all respects that which follows the administration of an active liver preparation to such persons. Within two or three days after therapy was instituted all 3 patients experienced an improved sense of well being, which was manifested by increased alertness and cheerfulness. The glossitis was relieved on the fourth or fifth day; regeneration of the lingual papillae was obvious on the fifth day. Simultaneously there was cessation of the diarrhea and increased appetite. Weight gains commenced on approximately the fifth to the seventh day of therapy. The initial increases in weight appeared to reflect water retention. They occurred rapidly and were accompanied by demonstrable edema and hemodilution, which disappeared at about the twelfth to the fourteenth day. At the latter time a slight weight loss occurred. Transitory edema appearing in treated cases of nutritional macrocytic anemia at the height of hemopoiesis has been noted by Holmes.[13] The subsidence of this edema has been followed by striking increases in body weight unaccompanied by evidences of water retention. These gains were accompanied by general betterment and an almost insatiable appetite.

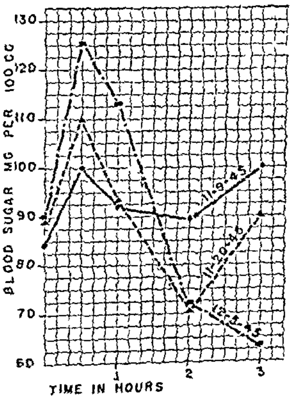

Fig. 6 (case 3).—Oral glucose tolerance curves. First curve made before treatment, second curve ten days after beginning of treatment and third curve twenty-five days after beginning of treatment

In relation to the gain in weight it is of interest to consider the alterations which were found in the glucose tolerance as indicative of improved absorption. All 3 patients exhibited abnormally flat oral glucose tolerance curves prior to treatment. Intravenous glucose absorption curves run on 2 of the patients were normal. The oral glucose tolerance was repeated on 2 of the patients following therapy. In both instances there was a return to an essentially normal curve after two weeks to a month following the institution of treatment with L. casei factor (figs. 3 and 6). If this abnormality indicates a faulty absorption of glucose in sprue, as is usually held, it would appear that synthetic L. casei factor is capable of correcting this defect in absorption from the gastrointestinal tract. Furthermore, its activity in this respect again resembles that of liver extract as illustrated by case 3 (compare figs. 6 and 7).

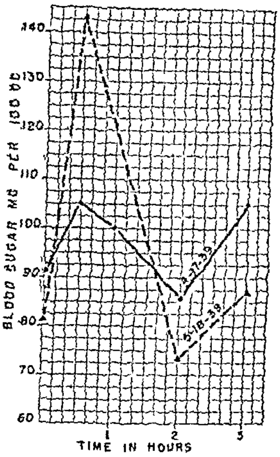

Fig. 7 (case 3).—Oral glucose tolerance curves made before and after treatment with liver extract during first hospital admission in 1939. Second curve twenty-seven days after beginning of treatment.

It is generally assumed that the steatorrhea in sprue is another evidence of impaired absorption,[14] although incontrovertible proof of this assumption has not been provided. It is well recognized that the steatorrhea may persist even after intensive liver therapy which results in a satisfactory clinical response. Neither of the 2 cases which we have followed with repeated stool analyses has shown a return to the normal fat content, although the diarrhea was promptly relieved. Furthermore, these patients have not exhibited an increase in plasma carotene content—another finding consistent with the continued presence of excess fat within the gastrointestinal lumen. Whether the finding of low serum carotene levels in sprue[15] is corrected following liver therapy is not known. It appears logical to expect it to be altered only in those patients in whom the steatorrhea is arrested following therapy, for it has been demonstrated that the continued presence of a nonabsorbed fatlike substance within the intestinal lumen interferes greatly with the absorption of carotene[16] and that carotene absorption is dependent on simultaneous fat absorption.[17] It is of interest that the fat extracted from the stools of our 3 patients was highly colored, with a yellowish red pigment suggesting carotenoid pigments. There has been a rise in serum vitamin A levels in 2 of these patients following therapy.

and a less abnormal vitamin A tolerance curve has been found. Only 1 (patient 2) has shown an increased serum carotene level. Repeated analyses of the stools of this patient have not been obtained.

The rapid relief of the symptoms of glossitis and the regeneration of the lingual papillae are worthy of comment, since it has been implied that the glossitis in sprue and in pernicious anemia may be due to niacin deficiency.[18] Our experience would indicate that this L. casei factor or some metabolite of it is responsible for the relief of this glossitis.

In our 3 patients treatment has brought about increases in all of the formed elements of the blood, i. e. red cells, white cells and platelets. The changes pertaining to red and white cells are shown in the respective charts. While the blood platelets were not at appreciably low levels before treatment, their approximate tenfold increase following treatment was striking and occurred in all 3 patients. These responses resemble those seen in vitamin M deficient monkeys successfully treated with liver extract, yeast or L. casei factor.[19]

Patient 2 showed a lag in hemoglobin as her red blood cells increased. This course is not infrequently seen in pernicious anemia at a comparable stage in treatment. It is of interest that she was six weeks post partum and presumably her iron stores were low. It was our plan to give her iron with the expectation of obtaining a second response in reticulocytes, but she would not remain in the hospital sufficiently long to permit this. The finding of a moderate macrocytic anemia fifty-six days after completion of treatment leads us to predict that she has reached her peak of response and that a relapse is to be expected.

We are indebted to Dr. Paul F. Hahn of the Department of Biochemistry of Vanderbilt University Medical School for the measurements of radioactive iron absorption by these patients. The percentage of the ferrous iron absorbed in all 3 cases was much below that level found in iron deficiency anemia. This is of particular interest in case 2, in which during therapy a hypochromic anemia developed. The discussion of the interpretation of this failure to absorb iron in untreated sprue is outside the scope of the present communication.

Bone marrow obtained by sternal aspiration was examined before and after treatment in cases 2 and 3. Prior to treatment a typical megaloblastic arrest was seen. In case 2 this largely megaloblastic picture was replaced five days after institution of treatment by normoblastic predominance, which persisted on the eleventh day of therapy. It is to be recalled that at this time the macrocytic anemia was becoming hypochromic and microcytic. In case 3 the bone marrow had returned to normal ten days after treatment was begun.

The accompanying table compares the reticulocyte peaks observed in these 3 patients with sprue with those predicted in patients with pernicious anemia at the same level of red blood cells.[20] It is seen that 2 of the 3 patients obtained slightly lower reticulocyte responses than predicted for patients with pernicious anemia of the same grade of anemia, while the response of 1 patient greatly exceeded that predicted. Satisfactory increases in red blood cells occurred in all patients.

Although it is well to reserve a discussion of the probable relationship of this material to the antisprue factor present in liver extracts until the chemical nature of these factors are revealed, certain observations are pertinent. This material occurs in liver and in many liver extracts. It is effective when injected in the treatment of both sprue and pernicious anemia;[21] hence it has an activity corresponding to Castle's maturation factor. It seems logical to assign to this factor at least part of the antisprue activity of liver extracts. This may not be the only effective antisprue factor; however, it appears to be a satisfactory one for therapeutic use.

The present evidence suggests that the administration of this L. casei factor will result in a satisfactory response in cases of sprue, pernicious anemia, pernicious anemia of pregnancy and nutritional macrocytic anemia —all conditions which are associated with a marrow characterized by a megaloblastic arrest. Spies and his associates[22] have reported on the use of this material in a series of inadequately diagnosed macrocytic anemias and have implied thereby that it is efficacious in the treatment of all macrocytic anemia. Unpublished data of ours indicate that the factor is effective only in those macrocytic anemias with hyperplastic primitive marrow. So-called "dysplastic" and "aplastic" anemias have failed to respond to this material even though examination of the peripheral blood indicated a macrocytic anemia in some of these. Our experience with the refractory group of anemias has confirmed that of Watson and his associates.[23] One may predict, therefore, that this synthetic L. casei factor will be of value in treating those macrocytic anemias which are accompanied by hyperplastic marrow and which are known to respond satisfactorily to liver preparations.

Reticulocyte Peaks

	Maximum Reticulocyte Response Calculated for Pernicious Anemia	Maximum Reticulocyte Response Observed in Cases of Sprue
Case 1	23	15
Case 2	26	43
Case 3	15	11

The relationships which have been outlined have led us to suggest that vitamin M deficiency in the monkey is the experimental analogue of sprue in man.[24] Since there appear to be a number of related factors which have hemopoietic activity in animals and confusion has arisen in the nomenclature of these substances, it is tentatively suggested that those factors of this group

which possess similar hemopoietic activity for primates may conveniently be referred to as the vitamin M group. Such a usage would be consistent with the previous practice in naming the vitamins. Furthermore, it would be justified by the chronological order of the discovery of the biologic effect of this group of substances. The term "folic acid" has been so loosely employed that its further use in reference to this group of compounds can but lead to confusion.[25]

The aforedescribed responses demonstrate that all of the cardinal manifestations of sprue which are amenable to liver therapy undergo remission following the intramuscular injection of this synthetic L. casei factor. Study for longer periods of time will determine whether the fat content of the stools and the x-ray pattern of the gastrointestinal tract return to normal following such therapy. It is to be emphasized that these remissions have persisted for at least two months since the cessation of therapy. The response of 1 patient previously treated with liver extract has been more complete on the doses of L. casei factor used than was his previous response to liver extract. It is worthy of comment that patient 2 had previously received from her local physician a series of injections of thiamine, niacin, riboflavin, pyridoxine and pantothenic acid for a five weeks period with no beneficial effects.

The doses administered to these 3 patients are probably in excess of the minimal amount which would produce a maximal response. Moore and his co-workers[21] report a reticulocyte response in 2 cases of true addisonian pernicious anemia following the intravenous injection of 2 mg. per day of this factor. Jukes[26] states that the requirement of the chick for this L. casei factor is one-fifth to one-tenth that of its requirement for riboflavin. If a similar ratio holds in man, a maintenance dose would be of the order of 0.1 to 0.2 mg. per day, while curative doses may well be of the magnitude of a milligram daily. It should be pointed out that we have observed no local or systemic toxic effects from the administration of this material in the doses employed to some 12 persons who manifested a variety of blood dyscrasias.

Confirmation of our finding of the activity of this synthetic factor in cases of sprue has been reported from two other laboratories.[27]

SUMMARY

Intramuscular administration of synthetic L. casei factor in doses of 15 mg. per day has been followed by complete hematologic responses in sprue. The glossitis, diarrhea and absorption of water soluble factors have also responded to this substance as the sole therapeutic agent. The evidences of impaired fat absorption have not been altered in 2 cases by this therapy during a two month observation period. The serum carotene level in 1 case has risen. This substance or a precursor or metabolite of it would appear to be one of the active antisprue factors in liver extracts.

The resemblance of sprue to vitamin M deficiency in the monkey has led us to believe that the latter is the experimental analogue of sprue in man.

We propose that the group of substances related to L. casei factor and "folic acid" and which exhibit hemopoietic activity for primates be termed the "vitamin M group."

Clinical Notes, Suggestions and New Instruments

THE EFFECT OF ATABRINE SUPPRESSIVE THERAPY ON EYESIGHT IN PILOTS

COLONEL E. A. ABBEY and MAJOR E. A. LAWRENCE
Medical Corps, Army of the United States

In order to determine the effect of continued doses of atabrine on visual acuity, 1,127 pilots from the Air Transport Command were tested. None of these pilots had ever worn glasses; they were tested during their active tour of duty, which involved flying from India or Assam bases to China across the Himalayan mountains—the so-called Hump. The problem of vision is of singular interest in this type of flying, which is probably the most hazardous of any in the world; treacherous mountains and an ever changing atmosphere which requires a great amount of instrument flying keep the pilot constantly alert and obviously require an absolutely faultless vision.

Effect of Suppressive Atabrine on Eyesight and Skin in 1,127 Cases

	Number of Cases	Percentage
Age		
20 to 25	588	52.1
26 to 30	393	34.9
31 to 35	128	11.4
36 to 40	18	1.6
Acuity		
No change	971	86.1
Better	114	10.1
Worse	42	3.8
Pigmentation of skin		
None	180	16.0
Mild	501	44.5
Moderate	428	37.9
Severe	18	1.6
Duration of atabrine ingestion		
1 month	81	7.2
2 months	55	4.9
3 months	67	6.0
4 months	523	46.4
5 months	259	23.0
6 months	110	9.6
7 months	17	1.5
8 months	9	0.8
9 months	3	0.3
10 months	3	0.3

Every pilot is required to pass the physical examination for flying status, the so-called 64 examination, at least once a year and oftener if prolonged hospitalization has occurred or following accident. Visual acuity was recorded from such an examination prior to the ingestion of suppressive atabrine. Visual acuity was then performed after varying months of atabrine ingestion. The results are given in the accompanying table.

If there was no alteration in the visual acuity prior to and during atabrine ingestion the result was recorded as "no change." If improvement or deterioration of acuity occurred it was recorded as "better" or "worse." In no instance was there a change for better or worse greater than 5/20. Of note too is the fact that in the entire group the acuity prior to suppressive atabrine was either 20/20 or 20/15 vision. It at once becomes obvious that a change in acuity of such small degree is without practical significance, for it is well known that small temporary variations may occur normally as a result of mental and physical fatigue, loss of sleep, nervousness and the general state of health and well being of the examined subject. Only one sitting was required to determine the acuity

---

From the India-China Air Transport Command.

in order to conform as closely as possible with previous examinations, and no rest previous to the test was given. Such conditions would further tend to minimize, to a point of negligence, changes of minor degree in acuity, since many of the pilots were tested after long flight and others after a night of varying indulgences. We are therefore correct in assuming that in no instance, save for the 1 case presented here, was there a change in acuity of any practical significance.

In this group of pilots ages ranged from 20 to 40 years, with 85 per cent approximately lying between 20 and 30 and the remaining 15 per cent over 30. Obviously, age has been of no significance in the changing of acuity in spite of the natural tendency for the eyesight to become hyperopic as the years advance.

Suppressive atabrine is administered in this theater in an initial dose of 0.1 Gm. a day for five days followed by 0.2 Gm. (two tablets) a day for ten days and then 0.1 Gm., or one tablet, every day. Approximately 70 per cent of the pilots tested had been taking the drug between sixteen and twenty weeks, certainly a long enough time to alter acuity materially if this was to prove an untoward effect. It was suggested, but certainly not proved, that acuity may change, the deeper the dermal staining from the ingestion of atabrine. From the table it may be seen that 82 per cent showed a definite yellow hue to the skin, varying from an arbitrary "mild" to "moderate." It was noted that there was no correlation between length of time of ingestion and intensity of dermal staining; some men, for example, having taken the drug for eight months, showed only a mild yellow discoloration and others, having taken the drug for one month, showed a moderate or severe staining. It would appear that the degree of dermal staining is purely the result of an individual susceptibility to the ingested drug. Certainly too there is no correlation between the degree of staining and visual acuity; as a matter of fact, all 18 cases that showed a severe reaction, in that the skin was deeply yellow stained, presented no change in acuity at all.

One case of apparently pure ocular sensitivity to atabrine has been brought to our attention and was instrumental in initiating this study. It occurred in a medical officer (A. E. S.) aged 35 who had been taking atabrine for twenty-one days prior to the onset of symptoms. These consisted of blurring of vision and a halo around lights during the dark hours. The visual acuity in both eyes was 20/30 prior to ingestion and 20/50 in both eyes three weeks after taking the drug. Ophthalmoscopically only a hazy cornea was noted; by slit lamp there were tiny patches of corneal edema. With discontinuance of atabrine suppressive therapy the acuity returned to 20/30 in both eyes in sixteen days, and all objective findings returned to normal. Following a rest period atabrine was again administered, with recurrence of all symptoms and objective findings as listed in some twenty-one days; return to normal vision occurred at this time in twenty-five days. There seems to be little doubt that in this case there was a definite sensitivity to the drug, manifested by patches of corneal edema and decrease in visual acuity.

CONCLUSIONS

1. The continued use of atabrine in doses of one tablet (0.1 Gm.) a day appears to have no effect on visual acuity, except in a highly sensitive and rare individual.

2. Older persons on suppressive atabrine therapy do not differ from the younger group as far as visual acuity is concerned.

3. There is no correlation between the depth of dermal discoloration and change in visual acuity.

4. The depth of dermal staining appears to be as a result of individual sensitivity and not related to the length of time atabrine has been taken.

Social and Natural Science.—Scientific discoveries do not fall from a clear sky. What actually happens is that the mind finds solutions to challenging problems only after long contact. How solutions finally dawn, not unexpectedly, is occasionally narrated after most careful autobiographical exploration as the long list of simultaneous discoveries demonstrates.—Cohn, Alfred E.: Minerva's Progress, New York, Harcourt, Brace & Co., 1946.

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

The following statement has been authorized for publication by the Council.
Austin Smith, M.D., *Secretary.*

CHLOROQUINE, NONPROPRIETARY NAME FOR SN 7618

The Board for Coordination of Malarial Studies has requested the Council on Pharmacy and Chemistry to give consideration to the recommendation of a nonproprietary name for a new antimalarial compound known so far as SN 7618. It has the chemical structure of 7 chloro-4 (4-diethylamino-1-methylbutylamino) quinoline. Chloroquine has been proposed as the nonproprietary name.

The Council has been informed that the compound is covered by a German patent which has been assigned to the Winthrop Chemical Company, although all of the work in developing its antimalarial properties and usage has been done by the government contractors working under the Office of Scientific Research and Development. The Council has been cognizant of the value of the cooperative studies which have been undertaken during the war. It feels that every effort should be made to encourage this and similar work and to make available as soon as seems expedient the results of the studies so that they may be applied for the good of humanity. The adoption and use of appropriate nonproprietary names for truly useful drugs would seem to be a step in this direction.

The Council has voted to recognize Chloroquine as a nonproprietary name for the antimalarial substance sometimes described as SN 7618.

Council on Foods and Nutrition

ACCEPTED FOODS

The following additional foods have been accepted as conforming to the Rules of the Council on Foods and Nutrition of the American Medical Association for admission to Accepted Foods.

RESEARCH IN AVIATION MEDICINE FOR THE GERMAN AIR FORCE

A report[1] recently released by the United States War and Navy departments on German research in aviation medicine concerns, among other subjects, pilot ejection, emergency procedures for escape from pressurized cabins at high altitudes, the effect of high wind velocities on the human head, thorax and abdomen, the liaison approach between aircrew and machine being operated to improve efficiency of operation and research and the development of the personnel parachute. The Germans have developed a parachute emergency oxygen apparatus which consists of a series of high pressure cylinders arranged in a circular manner to form a flat plate about an inch thick. The cylinders are connected to an outlet valve through a narrow tube, which is about 1 meter long and which acts as a metering orifice. The entire assembly is flat and fits into a pocket in both seat and backtype parachutes. During normal flight this emergency system is connected to the main aircraft oxygen system. A ripcord attaches the parachute assembly to the aircraft seat and, when the pilot wishes to leave the airplane, that portion of the emergency system which is attached to the main oxygen system is detached and the emergency oxygen flow valve is opened.

In their experiments on acceleration they measured the systolic and diastolic pressures every fifteen seconds and found that acceleration of 3 g (acceleration of gravity) can be sustained for long periods without difficulty. Above 3 g visual and mental disturbances began. The pulse rate increases rapidly in all trials. G tolerance increases during digestive processes and with addition of carbon dioxide to inhaled mixtures. Use of abdominal bands did not increase g tolerance. To sustain g higher than 3 it is necessary to place the men in horizontal positions.

It is pointed out that visual acuity is only one function of the eye. Other eye functions associated with functions of the brain consist of (*a*) the finding of objects, (*b*) the recognition of objects and (*c*) orientation. In contrast to the visual acuity, these functions can be well trained. Therefore investigations of the higher associated functions are of the greatest practical value to aviation, as shown by the "Rhenshaw System" in the AAF. A test manometer was developed by slight modification of a standard sphygmomanometer for the purpose of measuring the permeability of the capillaries. It was found that pressure of 100 to 200 mm. of mercury was necessary to suck blood out through the skin in normal subjects and considerably less in pathologic subjects. Altitude adaptation could be developed by a stay of at least eleven days in the mountains at an altitude of at least 7,000 feet combined with a great deal of sport, good food and sleep. The limit of the adaptated man's altitude tolerance will be between 26,000 and 31,000 feet on the average without oxygen, although some men get to 33,000 feet. With oxygen the limit is 3,300 feet higher than normal, and man can fly without pressure cabins up to 45,000 feet. The time reserve of an adaptated man at 39,000 feet is one to one and a half minutes. Investigations on the effectiveness of drugs and physical stimulants to improve man's ability to work revealed that caffeine results in great irritability of the nervous system combined with loss of confidence; a mixture of caffeine and metrazol gives much better results; diphenylhydantoin has a depressing effect; morphine induces a desire to rest and to sleep; amphetamine is a good stimulant but results in a hangover. Appreciable improvement in ability and willingness to work was apparent after several Finnish baths (the Sauna) and exposure to sunlight.

An interesting development in eye prostheses is one with a photocell, an amplifier and a sound producer. In this arrangement light is converted into sound. By help of a lens system it is possible to adjust different angles of view. This construction enables blind men to find their way and to obtain sufficient orientation. There is also the development of a visual prosthesis changing the light into a tone in the same manner but combined with an ikonoscope. Thereby one has an ear image instead of an eye image. After a brief training period blind men could read any letter of the alphabet in two seconds. Investigations of other methods showed that this method seems to be the best one to read normal letters and to recognize landscapes.

Contrary to the general idea that rapid rewarming of men after a prolonged immersion in water accelerates collapse, they found that animals recovered much more readily after rapid rewarming than after slow rewarming. In experiments on parabiotic rats the controlled parabiotic circulation was clamped off during cooling, and this clamp was removed with rewarming. With slow rewarming the cold parabiotic did not recover; with rapid warming the cold parabiotic recovered and the control parabiotic showed no ill effects. Rapid warming of animals that were cooled to almost lethal temperatures resulted in greater recovery than slow warming.

---

[1] Research in Aviation Medicine for the German Air Force (Report 251), Office of the Publication Board, Department of Commerce, Washington, D. C.

The information contained in the report was obtained by our investigators who visited the experimental laboratories in Germany and interviewed the research workers. The information is interesting chiefly because it offers a basis for comparison between our own state of knowledge with regard to problems associated with aviation and that of the enemy. On the whole, the German aviation science does not reveal any successful solving of problems that our own investigators have not tackled and solved.

FREUND'S EMULSIFIED VACCINES

In 1942 it was shown by Freund[1] and afterward confirmed by Friedewald that the immune response of animals may be prolonged and often elevated by injecting antigens in the aqueous phase of saline in liquid petrolatum emulsions.[1] Applying the emulsion technic Mudd and his associates of the University of Pennsylvania subsequently attempted to improve the immunologic response to dysentery vaccines.[2] Falba, a stabilizing agent derived from lanolin, was mixed by an electric stirrer with a saline suspension of alcohol killed Shigella paradysenteriae bacilli until a smooth paste was obtained. Liquid petrolatum was then added and stirred until the emulsion was well diffused. The proportion of the constituents, antigen in saline: falba: liquid petrolatum was 1:1:4 respectively.

Thirty-five inbred white Swiss mice were given a single subcutaneous injection of 20 micrograms of S. paradysenteriae cells in 0.15 cc. of saline solution. A similar group was injected with 20 micrograms of the same vaccine in 0.15 cc. of liquid petrolatum. At appropriate intervals mice from each group were exsanguinated and their pooled serum titrated for specific agglutinins. With the saline vaccine the agglutinin titer reached a maximum of 40 units by the end of one week. The titer then declined to 4 units by the end of six weeks, at which level it remained practically constant till the end of the experiment (twenty-two weeks). With the emulsified vaccine the titer rose to 256 units by the end of ten weeks and remained at this high level till the fourteenth week. After the fourteenth week the titer gradually fell to 32 units by the twenty-second week. The peak titer with the emulsified vaccine was thus six times the peak titer with the saline vaccine. By using larger doses with other groups of mice the peak titer was increased to as much as 1,280 units, or thirty times that of the saline control.

In a second series of tests with the same technic, groups of rabbits were injected subcutaneously with two doses of 25 micrograms each of the same vaccines. The doses were given three days apart. Sample bleedings were taken from the ear veins at appropriate intervals and the pooled serum was titrated by the mouse protective test. With the saline vaccine there was a twenty-fivefold increase in mouse protective titer by the end of two weeks. The titer then fell to a fivefold increase by the end of four weeks and to a twofold increase by the end of thirty weeks. With the emulsified vaccine the titer rose to a fiftyfold increase by the end of six weeks and remained at this high level for about six weeks. The titer then slowly decreased till the end of the experiment (thirty weeks). The Freund emulsion technic, therefore, increased the antibody response twofold and prolonged the period of effective immunity at least sevenfold.

Successful clinical trials of Freund's emulsion technic have been reported by Henle[3] of the department of pediatrics, University of Pennsylvania. Centrifugally concentrated influenza virus vaccines of type A and B were selected as the stock vaccines. Half of each vaccine was emulsified in 1 part of falba and 4 parts of liquid petrolatum. The other half of the same vaccine was diluted 1:4 in buffered saline solution to serve as a control. Eighty female subjects received subcutaneously 0.3 cc. of the emulsified vaccine either in a single dose or as a divided dose in two simultaneous injections. A similar group of 80 female subjects was injected in the same way with 0.3 cc. of the saline vaccine. Individuals of both groups were bled before vaccination and at the end of two weeks and of one, two, three and six months. The serums were tested individually by the Hirst technic[4] for their ability to inhibit chick red cell agglutination by influenza virus A and B.

With the saline vaccine the geometric mean of the individual antibody titers reached a maximum of about 250 units by the end of two weeks and then gradually decreased to about 150 units by the end of six months. At the end of six months less than 60 per cent of the individuals given this control vaccine had titers of more than 128 units. Clinical experience has shown that 128 units is the minimum effective prophylactic titer.[5] With the emulsified vaccines a maximum titer of about 700 units was reached by the end of two months, with but slight decrease in this titer by the end of six months. At the end of six months 95 per cent of all individuals given the emulsified vaccine had titers well above the minimum protective level (128 units).

In these clinical tests, nodules of varying dimensions could be palpated in the subcutaneous tissues of most individuals. These gradually decreased in size. In most cases they disappeared spontaneously by the end of the observation period. In only two of the one hundred and twenty injections with the emulsified vaccines were abscesses noted about two months after the injection. Only one of these had to be drained surgically. Henle regards this number as not too discouraging in the light of earlier experiments with alum precipitated toxoids.

Application of Freund's emulsified antigens to allergic desensitization and to the production of commercial antiserums have not yet been reported. No fully satisfactory theory has thus far been proposed to account for the evident superiority of the emulsified vaccines.

Current Comment

PSYCHIATRIC EXAMINATION OF RUDOLF HESS

The role of the psychiatrist in the trial of the leading Axis war criminals has attained historical significance. This significance derives in a large measure from the fact that the psychiatric panel was appointed by the International Military Tribunal and reported its findings direct to that body. The panel consisted of three representative Russian psychiatrists, three British, one French and three American. The American psychiatrists, Dr. Nolan D. C. Lewis, professor of psychiatry, Columbia University College of Physicians and Surgeons, Dr. D. Ewen Cameron, professor of psychiatry, McGill University Faculty of Medicine, and Paul L. Schroeder,[1] Colonel, M. C., professor of psychiatry, University of Illinois College of Medicine, reported:

> We find, as a result of our examinations and investigations, that Rudolf Hess is suffering from hysteria, characterized in part by loss of memory. The nature of this loss of memory is such that it will not interfere with his comprehension of the proceedings, but it will interfere with his response to questions related to his past and will interfere with his undertaking his defense. In addition, there is a conscious exaggeration of his loss of memory and a tendency to exploit it to protect himself against examination. We consider that the existing hysterical behavior which the defendant reveals is also initiated as a defense against the circumstances in which he found himself while in England, that it has now become habitual and that it will continue as long as he remains under the threat of imminent punishment, even though it may interfere with his undertaking a more normal form of defense. It is the unanimous conclusion of the undersigned that Rudolf Hess is not insane at the present time in the strict sense of the word.

The psychiatrists were permitted to study these defendants as impartial workers utilizing the scientific method. The procedure removed the restriction imposed on the expert witness in civilian courts in both criminal and civil trials in that they served neither the prosecution nor the defense. Because such a procedure is well-nigh unique in criminal jurisprudence, it has historical interest. The appointment of psychiatrists from four geographically widely separated countries, speaking three different languages and coming from other cultures, assured a diversity of point of view and breadth of approach. The tribunal did not limit the psychiatrists to direct categorical replies; it authorized a report made in the form which commended itself to the examiners. This is likewise unique in court practice. The hearing of the tribunal on Nov. 30, 1945 concerning the mental state of the defendant was noteworthy on several counts. First among these is the remarkable degree of accord revealed in the reports of the groups of psychiatric experts representing the four countries responsible for the trial. This essential agreement between the groups, whose examinations, with the exception of that of the French, who participated in all three, were carried out separately, strengthens the conclusions of the psychiatric panel. The investigation of the defendant's behavior brought out his great instability as an important factor. Within the period of four years his record included a great variety of symptoms, delusions of persecution, two suicidal attempts, two periods of hysterical amnesia, various bodily symptoms such as abdominal cramps, which apparently are of neurotic origin, and finally his last dramatic outburst. These abnormalities of behavior have appeared and vanished as the pressures to which he has been subjected since he broke away from his established position in the Nazi hierarchy have waxed and waned.

CHOLERA STUDIES IN CALCUTTA

In a control experiment on the treatment of cholera in a highly endemic or epidemic area of India,[1] patients were taken in rotation as they were admitted to the hospital and assigned to the following groups according to the treatment given: A, sulfaguanidine; B, control; C, sulfadiazine; D, penicillin, and E, sulfadiazine and penicillin combined. All patients received supportive treatment in the form of intravenous, hypertonic and isotonic solution of sodium chloride and oral stimulants as indicated to offset dehydration, emaciation and circulatory failure. Group A received 3 Gm. of sulfaguanidine every four hours for three days and twice daily for the next three days, until a total of approximately 72 Gm. had been given. Group C received sulfadiazine 1 Gm. every four hours for the first day and 2 Gm. every four hours for the following two days, making a total of 30 Gm. Group D received an initial dose of 100,000 units of penicillin administered intramuscularly and 25,000 units every four hours thereafter for a total of 200,000 units. Group E received the combined treatments of groups C and D. It became apparent during the investigation that the usefulness of the therapeutic agents to the acutely ill patients could not be fully established because of the rapid progression into a state of shock, collapse or death before the drug could be effective in combating the infection. The salines administered were sufficient to offset dehydration, but the patients would lapse into shock and die of circulatory collapse. Results with plasma administration to combat shock and prevent collapse were much more encouraging. The circulatory response was definite, the heart sounds became strong and cyanosis disappeared quickly. The introduction of the plasma factor into a given group apparently lowered the death rate of that group.

[1] Office of U. S Chief of Counsel, APO 403, U. S Army, Dec 14, 1945.

[1] Summary of a study taken from Epidemiology Unit No 50.

so as to give undue credit to the value of the drug used. It was believed, therefore, that a much more accurate picture could be obtained by reclassifying all treated cases and placing them in three groups: (1) patients treated with plasma in addition to chemotherapy, (2) patients receiving chemotherapy alone and (3) a control group consisting of all patients who had not received treatment or who had insufficient treatment or only supportive treatment. In the first group the death rate was zero, in the second group the death rate amounted to 1.1 per cent, while in the third group the death rate was 38.3 per cent. The value of chemotherapy was clearly demonstrated. The dramatic effect of plasma is still more evident if the shock or collapse cases are segregated and tabulated. There were, in all, 78 severely ill patients in that group. The results in the group showed a mortality rate of 95.8 per cent for the control group, 15.8 per cent for chemotherapy alone and no mortality in the group treated with plasma plus chemotherapy. It appears, therefore, that chemotherapy with supportive treatment will effectively lower the expected death rate in cholera.

PIONEER HEALTH TELECASTS

THE JOURNAL this week (page 802) announces experimental telecasts over television station W9XBK carried out by the Bureau of Health Education in cooperation with the station management. Television offers a medium which has some of the characteristics of radio and some of those of the stage, appealing primarily to the eye rather than to the ear as does radio. Television should be a particularly useful medium for the demonstration type of educational program. Television makes possible demonstration and exhibit, appealing both to the visual and to the auditory pathways to the brain. Procedures difficult to describe by word of mouth alone can be visually demonstrated by bringing before the camera such procedures as the taking of blood pressure, bandaging, first aid, blood counting and the use of the x-rays. The procedure in a television program may be briefly outlined by describing what is probably the first medical telecast, made by the Director of the Bureau of Health Education as a guest on the program entitled "Tea Time," by Harriet Hester. The program was opened by the two participants sitting at tea in a living room and beginning a conversation about nutritionally adequate lunches. They then adjourned to a kitchen setup, where with actual foods and models they set up on a table three nutritionally adequate lunches consisting of different kinds of sandwiches, fruit, milk, skim milk or cocoa and ice cream for dessert. The arrangement of these lunches in attractive patterns on a table was accompanied by an informal conversation in which the nutritional values of each item were illustrated. In similar manner, by demonstration and explanation with the use of enlarged charts, curves, models, pictures and actual objects, other topics can be demonstrated visually while they are being explained. For the present the television audience is limited. In metropolitan areas there are a few hundred television receiving sets. Telecasting is on an experimental basis. Methods and technics can be developed so that the medical profession will be ready in the future to make use of this new medium as it has used older mediums, such as the radio and the printed page, effectively.

DETECTING RADIATION HAZARDS

A recent release from the University of Rochester reveals many heretofore unpublicized aspects of research connected with the atomic bomb. The medical aspects of the research were organized in ten divisions. Among the most important was the development of methods to protect the employees; of the thousands employed in the plants not a single one was injured by any of the new and peculiar hazards of the work. Animal investigations on the toxicology and pharmacology of uranium compounds established criteria for tolerance levels. Methods of analyzing the urine of employees were devised to determine the extent of exposure and to estimate the amount of radiation exposure which could be tolerated by human beings. A method of taking finger impressions in wax was devised and employed on the workers handling radioactive materials in atomic plants. This permitted the determination of when, if at all, employees began to show changes in the skin as a result of contact with the materials handled. One division studied the blood of large groups of animals, completing over 100,000 analyses. Geneticists studied the effects produced on the offspring of mice and fruit flies which had been exposed to radiation. Some 277,000 mice and 50 million fruit flies were bred and observed. The application of the vast amount of data gathered by the University of Rochester group, of which that cited is only an example, can hardly be predicted, but the results will certainly be significant in the fields of metabolism, cancer, hematology and physical medicine.

DEATH STATISTICS AS INDEX OF EFFICIENCY OF CANCER SERVICE

In the United States cancer of the breast in 1943 caused 16,140 deaths, of the uterus 16,968, of the larynx 1,490, of the tongue 1,231, of the lip 661.[1] In Chicago in 1944 cancer of the breast caused 505 deaths, of the uterus 583, of the larynx 75, of the tongue 48, of the lip 11.[2] In 1942 cancer of the breast in England[3] caused 7,877 deaths, of the uterus 5,094, of the larynx 1,206, of the tongue 1,033, of the lip 290. These forms of cancer are curable in their early stages; the figures cited therefore indicate grave shortcomings in clinical cancer service. Many agencies are now urging on the public and the medical profession the vital importance of early diagnosis with prompt adequate treatment of cancer. Increasing stress is being placed on the need of more modern facilities for cancer service. States, cities and other communities as well as closed groups like the Veterans Administration in their death statistics of cancer have an invaluable index of the efficiency of cancer service.

MEDICINE AND THE WAR

ARMY

ARMY AWARDS AND COMMENDATIONS

Captain Bernard J. Ryan

Capt. Bernard J. Ryan, Chateaugay, N. Y., while serving with the 506th Parachute Infantry of the 101st Airborne Division, was awarded the Silver Star and the Silver Star with Oak Leaf Cluster. He was also awarded the Bronze Star "for meritorious service in connection with military operations against an enemy of the United States in France, Holland and Belgium. He received the Purple Heart for wounds received in action at Bastogne, Belgium, in January 1945. According to the citation accompanying the Silver Star award, "Capt. Bernard J. Ryan, while serving with the Army of the United States, distinguished himself by gallantry in action. On Oct. 5, 1944, after two hours of constant mortar and artillery fire, his battalion was subjected to an attack by a strong enemy force in the vicinity of Opheusden, Holland. The battalion aid station located in the town was under heavy enemy fire from mortars, artillery and small arms. Captain Ryan, assistant battalion surgeon, continued operating the aid station despite the enemy fire and on several occasions made his way to the front lines to treat and evacuate wounded personnel in the midst of enemy machine gun and shell fire. He refused to move the aid station to the rear although it had received two direct hits, for such a move would detract from the efficient evacuation of casualties. Captain Ryan, disregarding enemy fire and the possibility of being captured, treated a large number of American and British casualties, saving many lives. When the battalion was relieved and he was ordered to set up his aid station in the rear, Captain Ryan remained at his front line post until every casualty had been evacuated. Throughout the action he displayed outstanding devotion to duty, skilful application of his superior knowledge and complete disregard for his personal safety. His actions were in accordance with the highest standards of the military service."

The award of the Oak Leaf Cluster to the Silver Star was accompanied by a citation giving a further example of Captain Ryan's gallantry: "On Jan. 13, 1945 in the vicinity of Foy, Belgium, the advance elements of an attacking company were subjected to heavy enemy artillery and small arms fire and sustained heavy casualties. After Captain Ryan had established his aid station in a house near the forward elements it became the target for enemy machine gun and small arms fire, which killed one man and wounded three. Disregarding the enemy fire, Captain Ryan was wounded. In spite of his wound, he continued to care for his patients and to direct the functions of the aid station. The outstanding devotion to duty and courage of Captain Ryan proved instrumental in saving the lives of many American soldiers. His actions were in accordance with the highest standards of the military service." Dr. Ryan graduated from Harvard Medical School, Boston, in 1940 and entered the service Feb. 11, 1943.

Captain David F. Kohn

Capt. David F. Kohn, Mount Pocono, Pa., was recently commended by Brig. Gen. R. F. Kernan, commanding officer of the 27th Division Artillery. Stated General Kernan in the citation accompanying the commendation, "It has been brought to my attention that during the battles for Saipan and Tinian Islands, Marianas Group, from June 17 to July 31, 1944, you performed your duties as battalion surgeon in a skilful and highly commendable manner. Your devotion to duty and untiring labor no doubt kept many men in action who might otherwise have been causalties. Your performance as a soldier and a medical officer bring credit both to your profession and to the military service." Dr. Kohn graduated from the University of Pennsylvania School of Medicine, Philadelphia, in 1931 and entered the service Feb. 1, 1941.

Lieutenant Colonel Bert Bradford Jr.

Lieut. Col. Bert Bradford Jr., Charleston, W. Va., was recently awarded the Legion of Merit "for exceptionally meritorious conduct in the performance of outstanding service, as chief of surgical service, 45th Evacuation Hospital, from Aug. 2, 1944 to May 10, 1945. Lieutenant Colonel Bradford skilfully supervised the work of his section and teams attached to his unit in a manner which insured the highest quality of surgical treatment to wounded men. Particularly noteworthy was his introduction in the hospital of the most recent developments in the treatment of wounds of the hand and vascular injuries. By his demonstration of professional ability, sound judgment and untiring effort Lieutenant Colonel Bradford contributed greatly to the success of his unit's operation, and his services reflect highest credit on himself and the armed forces of the United States." Dr. Bradford graduated from Washington University School of Medicine, St. Louis, in 1935 and entered the service Sept. 25, 1940.

Colonel Johnson McGuire

For his record as medical consultant for the Fifth Service Command, Col. Johnson McGuire, Cincinnati, was recently awarded the Legion of Merit. The citation accompanying the award stated that "by reason of his unfailing tact, judgment and superior professional qualifications Colonel McGuire was, in a great measure, responsible for the outstanding quality of medical treatment by hospitals of the Fifth Service Command." Dr. McGuire graduated from Johns Hopkins University School of Medicine, Baltimore, in 1924 and entered the service June 19, 1943.

Captain Monroe Cohen

Capt. Monroe Cohen, Brooklyn, was recently awarded the Bronze Star for distinguished service as battalion surgeon "in connection with military operations against the enemy of the United States from July 4, 1944 to May 1, 1945 in France, Luxemburg, Belgium and Germany." Dr. Cohen graduated from Long Island College of Medicine, Brooklyn, in 1942 and entered the service July 3, 1945.

Captain Stanford Borne

Capt. Stanford Borne, Brooklyn, was recently awarded the Bronze Star "for meritorious service in connection with military operations against the enemy from March 8, 1945 to April 15, 1945 in Germany. As clearing platoon leader Captain Borne distinguished himself by his untiring efforts, expert medical treatment and evacuation of the wounded, under adverse conditions." Dr. Borne graduated from Long Island College of Medicine, Brooklyn, in 1941 and entered the service July 1, 1942.

Colonel Harry Penn Harper

Col. Harry P. Harper, Rochester, Minn., was recently awarded the Legion of Merit for establishing the first field hospital across the Rhine. Dr. Harper graduated from the University of Minnesota Medical School, Minneapolis, in 1937 and entered the service July 31, 1941.

Captain Nicholas J. Chiara

The Bronze Star and Purple Heart awards were recently presented to Capt. Nicholas J. Chiara, Brooklyn, for conspicuous service on Mindanao in June 1945. Dr. Chiara graduated from the Long Island College of Medicine, Brooklyn, in 1941 and entered the service July 1, 1942.

Major Manuel A. Bergnes

Major Manuel A. Bergnes, Teaneck, N. J., was recently awarded the Silver Star for action on Mindanao. Dr. Bergnes graduated from Long Island College of Medicine, Brooklyn, in 1941 and entered the service July 1, 1942.

PHYSICIANS SEPARATED FROM SERVICE

ARMY MEDICAL CORPS OFFICERS RECOMMENDED FOR/OR RELIEVED FROM ACTIVE DUTY

Alabama

Pilkington, John S., Capt., Uniontown.
Word, Samuel B., Col., 812 10th St., SW, Birmingham.
Zieman, John A., Capt., Route 1, Box 428, Mobile.

Colorado

Fowler, Harmon L., Lt. Col., 1279 Ogden St., Denver.
Freeman, Leonard, Major, 300 S. Gaylord St., Denver.
Hall, Henry L, Major, 1670 Williams, Denver.
Kimball, Merritt H., Lt. Col., 100 Metropolitan Bldg., Denver.
Luther, Ross D., Capt., 202 E. Bennett Ave., Cripple Creek.
McKeen, Harold R. Jr., Capt., 966 S. Josephine St., Denver.
Ozamoto, Isamu, Capt., 830 18th St., Denver.
Perkins, James M., Capt., 356 Marion St., Denver.
Plank, Joseph R., Major, 200 S. Eudora St., Denver.
Ramo, Leon, Lt. Col., J.C.R.S. Sanatorium, Spivak.
Rosenbloom, Meyer R., Capt., 768 Colorado Blvd., Denver.
Van Der Schouw, H. M., Capt., Lutheran San., Wheat Ridge.
Wade, Theodore E., Major, 720 W. Pitkin St., Pueblo.

Connecticut

Panettieri, Andrew J., Capt., 3084 Main St., Bridgeport.
Pepe, Anthony J., Capt., Norwich State Hospital, Norwich.
Pinn, Abraham S., Major, 75 Sherman Avenue, New Haven.
Sirica, Alphonse E., Capt., 22 McDonald Ave., Waterbury.
Smith, Frederick F., Capt., 84 Dixwell Ave., New Haven.
Thompson, Lloyd J., Col., 128 Beach Avenue, Woodmont.
Zujko, Alphonse J., Capt., 190 Broad St., New Britain.

District of Columbia

Chase, William W., Lt. Col., 1813 Parkside Drive, Washington.
Custis, Horace H., Capt., 1839 Irving St. N.W., Washington.
Kassan, Robert J., Major, 4503 4th St. N.W., Washington.
Kistin, Albert D., Capt., 2205 42d St. N.W., Washington.
Lafsky, Benjamin P., Lt. Col., 5421 7th St. N.W., Washington.
Lomack, C. L., 1st Lt., 2911 Sherman Ave. N.W., Washington.
MacBrayer, Reuben A., Lt. Col., 3733 T St. N.W., Washington.
Thompson, J. L. Jr., Lt. Col., 1735 20th N.W., Washington.

Florida

Borland, James L., Major, 1786 Challen Ave., Jacksonville.
Boughton, Herman, Major, 6601 Brevity Lane, Miami Beach.
Clark, Samuel J., Capt., 128 Patten Heights, Lakeland.
Edwards, George W. II, 1st Lt., 309 Cherokee Drive, Orlando.
Irwin, Thomas M., Major, 322 E. Central Ave., Orlando.
Jenkins, Leslie M., Capt., 3232 Emathla St., Miami.
Lytle, Carl S., Lt. Col., 29 Holder Block, Ocala.
Mitchell, William S., Major, 712 Daniel St., Orlando.
Reeser, Richard Jr., Lt. Col., 218 University Blvd., Daytona Beach.
Smoak, Philip L., Capt., 1907 Oakmont Ave., Tampa.
Snelling, William R., Major, Fernandina.
Soskis, Elbert J., Capt., Mulberry.
Torrado, Rene A., Capt., 541 Lincoln Road, Miami Beach.
Watson, Francis M., Lt. Col., 207 N. 5th St., Chipley.

Georgia

Etheridge, William N., Capt., 33 Maddox Drive N.E., Atlanta.
Fleming, Carlton A., Major, 1008 Hall Avenue, Tifton.
Hatcher, Milford B., Major, The Massee, 401 College, Macon.
Huie, Lynn M., Capt., Monroe.
McWhorter, Myrtus R., Capt., 1528 32d St., Columbus.
Nunnally, Harry B., Capt., Broad St., Monroe.
Paulk, James R., Capt., Moultrie.
Roberts, Luther J. Jr., Capt., Manchester Hotel, Manchester.
Porter, John E., Major, 501 E. 53rd St., Savannah.
Ragland, Frederick B., Capt., 205 King St., Dalton.
Rosen, Emanuel F., Capt., 609 W. 37th St., Savannah.
White, Cecil G. Jr., Capt., 2772 Alpine Road, Atlanta.

Indiana

Bartle, James L., Capt., 137 S. Franklin, Knightstown.
Baxter, James W. Jr., Capt., 1201 E. Spring St., New Albany.
Bennett, Jene R., Capt., 310 Pennsylvania Ave., Plymouth.
Blemker, Russell M., Major, 215 N. Franklin St., Greensburg.
Brown, Kenneth H., Major, 1654 Hedden Park, New Albany.
Browning, William M., Major, Indianapolis City Hospital, Indianapolis.
Crain, James W., Capt., Brooklyn.
Dittmer, Jack E., Major, 54 Lincolnway, Valparaiso.
Eicher, Palmer O., Capt., Belmont Road, Decatur.

Indiana—Continued

Ferrell, Mars B., Capt., 2035 N. Meridian St., Indianapolis.
Fullerton, Robert L., Capt., 1307 E. Michigan St., Indianapolis.
Gilliatt, James P., Major, 204 S. High St., Salem.
Graf, Jerome A., Capt., Bloomfield.
Kissinger, Knight L., Capt., 207 S. Wayne, Angola.
Lenk, George G., Capt., 2007 Maumee Ave., Fort Wayne.
McCarty, Virgil, Major, 403 W. Spruce, Princeton.
Price, Douglas W., Major, 402 N. Madison St., Nappanee.
Price, Sidney, Capt., 1137 W. 6th St., Marion.
Pyle, Harold D., Major, 115 N. Sunnyside Ave., South Bend.
Raphael, Isidor, Major, 305 Cadick Apts., Evansville.
Rothberg, Maurice, Major, 114 Wayne Pharmacal Bldg., Ft. Wayne.

Iowa

Brobyn, Thomas E., Major, 1309 Broad St., Grinnell.
Burch, Earl S., Capt., Dayton.
Coughlan, Charles H., Major, 706 Warden Apts., Ft. Dodge.
Foss, Robert H., Capt., Remsen.
Friedman, Herbert P., Capt., 711 E. Burlington, Iowa City.
Johnston, Charles H., Major, 24 W. 34th St., Des Moines.
Kast, Donald H., Capt., 4904 Pleasant St., Des Moines.
Kuntz, George S., Capt., 714 25th St., Sioux City.
Lowry, Frederick C., Capt., 1206 Yewall St., Iowa City.
Magaret, Ernest C., Capt., 416 N. Walnut St., Glenwood.
Nicholson, Clyde G., Capt., 301 S. Hill Avenue, Spirit Lake.
Putz, Arthur E., Major, Edgewood.
Robertson, Treadwell A. Jr., Capt., 211 W. 5th St., W. Liberty.
Robinson, Van Cooper, Major, 918 Des Moines St., Des Moines.
Rodawig, Donald F., Major, Spirit Lake.
Ryan, Martin J., Major, 3712 Jones, Sioux City.
Schulz, Arthur W., Lt. Col., Vet. Admin., Des Moines.

Kansas

Finney, Guy A., Lt. Col., 300 Woodlawn Avenue, Topeka.
Gradinger, Billens C., Major, 219 Poplar St., Halsted.
Hatcher, Albert C., Capt., 508 N. Washington, Wellington.
Hatton, Lloyd W., Capt., 709 Highland, Salina.
Huntley, Leslie L., Capt., 612 State St., Larned.
Irby, Pratt, Capt., 209 S. Main St., Ft. Scott.
Jones, Sam, Capt., 1825 Ash St., Hutchinson.
Loyd, Dale U., 1st Lt., St. Francis Hospital, Wichita.
Maser, George R., Capt., 5105 W. 65 Ter., Overland Park.
Nienstedt, John F., 1st Lt., Hartford.

Kentucky

Fearing, Oliver H., Capt., 2536 Algonquin, Ashland.

Kyle, Laurence H., Capt., E. Main St., Huntington.
Lightfoot, John H., 1st Lt., 78 Madison St., Fall River.
McGahey, Claud E., Capt., 14 Old Dee Rd., Cambridge.
Maher, Joseph J., Capt., 228 Brook Rd., Milton.
Meister, Abraham J., Lt. Col., 748 Bridge St., Lowell.
O'Brien, Walter M., Major, 1230 Hancock St., Quincy.
Olinick, Stanley L., Capt., 110 Madison St., Fall River.
Reder, Benjamin, Capt., 1022 Robeson St., Fall River.
Richards, Robert L., Major, 93 Marshall St., Watertown.
Rogers, Augustine T., Capt., 11 Summit St., Hyde Park.
Rosenheim, Frederick, Capt., 1 Clover St., Belmont.
Rubin, Abraham L., Lt. Col., 29 Commonwealth Ave., Pittsfield.
Ryan, Thomas F., Capt., Housatonic.
Simeone, Fiorindo A., Lt. Col., Peter Bent Brigham Hospital, Boston, (Home: Sackett Point Road, North Haven, Conn.)

Michigan

Anderson, Walter L., Major, 4411 Kensington Ave., Detroit.
August, Harry E., Major, 538 Maccabees Bldg., Detroit.
Bicknell, Edgar A., Capt., 13225 Birwood Ave., Detroit.
Blocksma, Ralph, Capt., 739 S. Prospect Ave., Grand Rapids.
Boyd, John O. Jr., Capt., 1206 Bethune W., Detroit.
Brooks, Nathan, Capt., 13725 Dexter Blvd., Detroit.
Burton, Horace F., Capt., East Tawas.
Clifford, Robert P., Capt., 10621 Lakepointe St., Detroit.
Diskin, Herman E., Capt., 3227 Fullerton Ave., Detroit.
Dowd, Bennard J., Capt., 1702 Greenlawn Ave., Kalamazoo.
Drolett, Donald J., Capt., 1623 W. Main St., Lansing.
Eaton, Robert M., Capt., 243 Aurora St. S.E., Grand Rapids.
Faulconer, Albert Jr., Major, 330 Walnut St., Rochester.
Fisher, Gordon F., Capt., 510 S. Jefferson St., Hastings.
Hall, Robert F., Capt., 1418 Fourth St., Bay City.
Harrington, Lawrence F., Capt., 5205 S. Martindale St, Detroit.
Knoch, Hubert S., Capt., 14149 E. Jefferson Ave., Detroit.
Koop, Chester S., Capt., Pinecrest Sanatorium, Powers.
La Core, Ivan A., Major, 18968 Northlawn, Detroit.
Levin, David M., Capt., 8821 Dexter Blvd., Detroit.
Patmos, Bernard, Capt., 138 E. Maumee, Adrian.
Schoenfeld, John B., Lt. Col., Cranbrook School, Bloomfield Hills.
Thieme, Elliott T., Lt. Col., 3 Geddes Heights, Ann Arbor.
Tuttle, Jay F., Major, New Berry State Hosp., Newberry.

Minnesota

Anderson, William H., Capt., 6th Avenue, E., Alexandria.
Ausman, Duane R., Capt., 1531 Portland Ave., St. Paul.
Berkson, Joseph, Col., 437 14th Ave. S.W., Rochester.
Boyer, Samuel H. Jr., Major, 2725 E. 6th St., Duluth.
Breslow, Lester, Capt., 24 11th Ave. N.W., Rochester.
Christensen, Llewellyn E., Capt., 214 Manitou St., Northfield.
Condon, William B., Major, Mayo Clinic, Rochester.
Dry, Thomas J., Major, Mayo Clinic, Rochester.
Fischer, Verrill J., Capt., 600 S. Brimhall St., St. Paul.
Graham, Frederick M., Capt., Mayo Clinic, Rochester.
Helferty, John K., Major, Tracy.
Hilger, David W., Major, 121 6th Ave. N.W., Rochester.
Lillie, John C, Major, % Midfields, R 2, Rochester.
Nickel, Walter R., Major, Mayo Clinic, Rochester.
Richardson, Robert J., Capt., Rushford.
Saliterman, Bernard I., Capt., 1423 Lakeview Ave., Minneapolis.
Scherling, Sidney S., Lt. Col., Taylors Falls.
Smith, Lucian A., Major, Mayo Clinic, Rochester.
Thompson, Floyd A., Major, 245 S. Snelling Ave., St. Paul.

Mississippi

Barron, James, Capt., 404 Alexander St., Indianola.
Beck, Otis H., Major, 1210 Main St., Greenville.
Boggess, Julian E. Jr., Capt., Macon.
Bolton, Eldon L., Lt. Col., 1118 West Beach, Biloxi.
Crull, Luther P., Capt., 1839 St. Mary St., Jackson.
Davidson, Arthur C., Capt., 1303 Main St., Greenville.
Davis, Floyd M., Capt., Van Vleet.
McRae, Matthew E., Capt., 1412 7th Ave., Laurel.

ORGANIZATION SECTION

ANNUAL CONFERENCE OF SECRETARIES AND EDITORS OF CONSTITUENT STATE MEDICAL SOCIETIES

Dr Lyman W. Mason, editor of the *Rocky Mountain Medical Journal,* Presiding

(Concluded from page 719)

Friday, February 8

EDITORIAL CONFERENCE

After an opening address by Dr George F Lull, Associate General Manager of the American Medical Association, Dr Mason presented a statement urging leadership by editors of state medical journals He said, in part, "It seems to me that the chief function of the state and regional journals is the dissemination of *medical news and medical* knowledge and developing a coordinated front in solving our problems to the public and to legislative bodies Certainly there ought to be some attempt within the realm of the editor to shape general medical opinion These efforts should stem from some consensus which has been urged in meetings like these and from the leadership of the American Medical Association, the Board of Trustees and the House of Delegates"

Dr Mason then introduced Dr Henry A Davidson, editor of the *New Jersey State Medical Journal*, who conducted a clinic on editorial problems The problems discussed included consideration of a "Letters to the Editor' page, discussed by Dr Carl B Drake (Minnesota), Dr Robert N Nye (Massachusetts), Dr George Kosmak (New York), Dr Holman Taylor (Texas), Dr Herman M Jahr (Nebraska), Dr Wilfrid Haughey (Michigan), Dr Creighton Barker (Connecticut) and Dr P E Blackerby (Kentucky).

Next was the receipt of books for review, the publication of reviews and the disposal of the books This was discussed by Drs Wilfrid Haughey (Michigan), Everett M George (Iowa), Henry A Davidson (New Jersey), R B Anderson (Texas) and Wingate Johnson (North Carolina)

The preparation and publication of editorials were discussed by Drs Henry A Davidson (New Jersey), Holman Taylor (Texas), Robert N Nye (Massachusetts), Thomas Murdock (Connecticut), George Kosmak (New York), Walter Donaldson (Pennsylvania) and Creighton Barker (Connecticut)

The next subject discussed was the reporting of county society activities, in which Drs Henry A Davidson (New Jersey), Herman M Jahr (Nebraska), George Kosmak (New York), Holman Taylor (Texas), Stanley Weld (Connecticut), Stewart G Thompson (Florida) and Wingate Johnson (North Carolina) participated

The publication of the activities of the Woman s Auxiliary was considered in discussions by Drs Henry A Davidson (New Jersey), Robert N Nye (Massachusetts) and P. P Chase (Rhode Island) Incidental to this discussion was a consideration of the publication of poetry

The meeting concluded with a presentation of the regulations on advertising of the Cooperative Medical Advertising Bureau

Saturday, February 9

The session of February 9 opened with a consideration of public relations published in The Journal for February 23 page 509

Following this presentation the conference considered prepayment medical care plans "Progress Toward a National Medical Prepayment Plan" was presented by Jay Ketchum executive vice president of the Michigan Medical Service The subject was discussed by Drs A W Adson (Minnesota) Creighton Barker (Connecticut), Morris Fishbein (Chicago), Walter Donaldson (Pennsylvania), A J Bowles (Washington), Frank Borzell (Pennsylvania), C G Spivey (South Carolina) and Thomas Murdock (Connecticut)

Postwar Medical Service

MINUTES OF MEETING OF JANUARY 12

Chicago, Illinois

The Committee on Postwar Medical Service met in the Board of Trustees Room of the American Medical Association Building, 535 North Dearborn Street, Chicago, Saturday, January 12, and was called to order by the Chairman, Dr Ernest E Irons, at 10 15 a m Those present were

Dr Walter L Bierring
Mr Graham L Davis
Capt William E Eaton
Dr Morris Fishbein
Dr E L Henderson
Mr J W Holloway Jr.
Dr Ernest E Irons
Dr Victor Johnson
Dr B R Kirklin
Major Gen George F Lull
Dr J J Moore
Col William N Piper
Father A M Schwitalla S J
Dr R L Sensenich
Dr H H Shoulders
Dr Austin E Smith
Lieut Col John K Voegtly
Col Floyd L Wergeland
Dr Olin West

Educational Internship and Residency Opportunities—Dr Johnson reported that the card reporting system inaugurated by the office of the Council on Medical Education and Hospitals was proving to be very helpful, that thirty to fifty returning medical officers come into the office every week and from one to two hundred written inquiries are received from such officers and answered each week Dr Johnson believed that at the present rapid rate of discharge it will be difficult to provide residencies in special fields for all desiring them and also that it appears to be doubtful that all those requesting certain residencies are qualified He thought that there would be about fifteen thousand who would want residencies of some sort. Dr Johnson stated that discussions had been carried on with the Advisory Board for Medical Specialties and a program worked out whereby the Council would approve certain residencies on a temporary basis and thus avoid the six to eight months delay that would be caused if approval procedures were to go through the regular channels The plan has been approved by the Council on Medical Education and Hospitals and by the executive committee of the Advisory Board for Medical Specialties but still awaits the approval of the individual specialty boards

With respect to the maintenance of residency quotas in the individual hospitals, Dr Johnson informed the Committee that the Procurement and Assignment Service had recently repeated its assertion that veterans would not be counted in the quotas at any time and that it will be announced soon that all quotas will be dispensed with about April 1 so that there will be no interference with the placement of veterans

Dr Johnson further stated that the deceleration of medical school programs is now possible as far as the Navy and Selective Service are concerned The Army has been urged to discontinue the Army Student Training Program and that will be done, in fact, a new directive has been issued which announces definitely the discontinuance of the program on June 30, 1946 Junior, sophomore and freshman students now in the medical schools under the A S T P will be demobilized on March 30, after which all schools can decelerate

Following Dr Johnson's statement there was discussion concerning approval of the temporary residency plan by the individual specialty boards, and Dr Kirklin said he had no doubt that the boards would approve it but that the plan should not be continued any longer than the emergency exists The Chairman agreed with Dr Kirklin, stating that the basic training demanded by the specialty boards is for the protection of the candidate and not of the boards and that while he was much in favor of the temporary approval plan he thought it should be emphasized officially that it is only an emergency measure Dr Kirklin pointed out that the candidates, under the temporary approval plan, still would have to take the examinations The Chairman stated that a further report on the situation would be expected at the next meeting

Enrolment of Medical Students.—Dr. Johnson, Chairman of the Subcommittee on Enrolment of Medical Students, reported that studies which have been made indicate that there is an entirely inadequate supply of students for 1946 classes; that data concerning this had been presented to the Inter-Agency Committee, but little encouragement was received, and that it still appears that no adjustment will be made by Selective Service toward the deferment of premedical students.

The Chairman presented to the Committee a telegram which had been sent, pursuant to instructions given by the House of Delegates of the American Medical Association, to the President of the United States, the Secretary of War, the Secretary of the Navy and many other officials of the government urging the correction of the regulations of Selective Service which make no provision for the deferment of young men qualified for entrance into premedical education, as follows:

> The House of Delegates of the American Medical Association in official session adopted the following statement: "The American Medical Association in common with all other medical groups views with apprehension the effects of the present regulations of Selective Service which make no provision for the deferment of young men qualified for entrance into premedical education. The American Medical Association believes that continuation of this policy will inevitably result in a lessened production of doctors at a time when more rather than fewer will be urgently needed. At this time, when veterans' needs, increased demands of military establishments for more doctors, and the greatly intensified concern with national health exist, the present program of Selective Service reducing the supply of doctors is indefensible. We therefore urge that the Military Affairs Committee of the House of Representatives and of the Senate take immediate steps to correct this situation in the interests of the public health and welfare." The House of Delegates directed that a copy of the statement be forwarded to each member of the Committee on Military Affairs of the House of Representatives and of the Senate, to the President, the Secretary of War, the Secretary of Navy, the Director of Selective Service and the Director of the Office of War Mobilization and Reconversion.

Replies to the telegram were received from many of those to whom it had been sent, and some of the replies indicated that the writers were in complete agreement with the Association's contentions. However, a reply received from the Acting Secretary of War, Mr. Kenneth C. Royall, read by the Chairman, was as follows:

> On December 10 the American Medical Association, through you as its Secretary, dispatched identical telegrams to President Truman, to the Secretary of War and to the Director of Selective Service. The President referred the telegram addressed to him to the Secretary of War. The Director of Selective Service replied on December 14 to the telegram addressed to him. A copy of his reply has since been furnished to the Secretary of War, who concurs in the position therein taken.
>
> Secretary Patterson is appreciative of the most helpful assistance repeatedly rendered to the War Department by the American Medical Association, which has been of especial value during the war crisis. However, after personally considering the Association's telegram, he did not feel that it would be sound policy to permit preferential treatment of any special group of individuals as to exemption from Selective Service, as this would be discriminatory against other groups and would, of course, lead to increased demands for special exemptions.
>
> Further it is believed—and hoped—that, as stated in the letter of the Director of Selective Service, the present return of veterans will very largely remove the condition with which the Association is concerned.

Father Schwitalla thought it would be well to try to find out just how many G. I.s there now are in college who plan to go on to medical school and was informed by Dr. Johnson that Dr. Harold S. Diehl had attempted to do this and had compiled some figures from colleges which normally supply between 15 and 20 per cent of the freshman classes to the medical schools. Dr. Diehl's figures indicate that these colleges have about one fourth of their usual supply of all types of premedical students, including G. I.s, who form a very small proportion of the whole. Selective Service did not appear to be impressed with the significance of the survey, maintaining that it did not represent what will be the case later on in 1946. In response to a suggestion from Father Schwitalla, Dr. Johnson said the Council on Medical Education and Hospitals would attempt to make a more comprehensive survey and, if possible, report thereon at the next Committee meeting.

Surplus Medical and Hospital Supplies.—Father Schwitalla, Chairman of the Subcommittee on Surplus Medical and Hospital Supplies, made the following statement: A meeting was held on December 13 of the Advisory Committee of the Surplus Property Board. This was the first time such a meeting has been held, and it was well attended. Existing regulations were discussed, particularly Regulation number 14 pertaining to disposal of property to nonprofit institutions, implementing paragraph 13 of the basic law (Public Law 457). There was also discussion by the Advisory Committee of the second set of regulations, having to do with the designation of the disposal agency. The question of who holds title to the property after it is called surplus was cleared up by a definition that the title passes into the hands of the Reconstruction Finance Corporation. The Army gives up all title to it and the money that comes in goes to the R. F. C. Regulation number 1 takes care of that point. Regulation number 15 takes care of disposal of real estate and affects whole hospitals; bids are being made for hospitals by groups of physicians. A struggle has been going on within the Surplus Property Administration with reference to centralization of authority, inventories and information, which are all decentralized. There are now thirty-one disposal agencies each having a measure of responsibility, which apparently accounts for the fact that with reference to surplus property it is difficult to make any general statement that affects the whole country. A matter for consideration was to what extent the government should go into the reassembling of surplus material, a process that might be necessary because of the manner in which most of it is stored. The Advisory Committee also discussed the matter of procedure and devised a new system. Under the old method an application for medical or hospital supplies originated with an individual or an institution. From the individual or the institution it went to the U. S. Public Health Service, which passed on the application, and from the Public Health Service it went to the Surplus Property Administration and, after approval by that agency, to the R. F. C. Thus four steps were required before final action could be taken. The Advisory Committee thought there could be no good reason why the applications could not be handled by one office, and that idea was embodied in a resolution outlining a new and simplified procedure. It is unfortunate that the final decision has not yet been made known. The material now available is only a small percentage of the thirty billion dollars' worth of property that finally will be available for disposal as surplus.

In the discussion following Father Schwitalla's statement, Dr. Fishbein stated that those responsible for disposal were putting most of their effort at present on selling the larger items—whole hospitals or buildings at one time—and are interested right now only in the mass disposal of such items.

In reply to a question from Mr. Davis concerning the amount of surplus medical and hospital supplies and equipment that actually would be usable, Father Schwitalla stated that, between July 31, 1944 and July 31, 1945, $18,900,000 worth of professional and scientific apparatus was declared surplus—mostly to dealers—and that during the same period $12,200,000 worth of that amount was inventoried but was not in condition that it could be offered for sale. In the same period $8,100,000 worth of drugs and medicines was inventoried but has not been offered for sale. Dr. Fishbein remarked that surplus drugs and medicines must be standardized through the Food and Drug Administration before being offered for sale.

Captain Eaton, in describing the method of disposal by the Navy, doubted that there would be much surplus medical property available through the Navy Department. He said that much of it was overseas and very likely would be left there as not worth bringing back, and that the Navy probably would itself use most of its own surplus medical property.

The Chairman requested the Subcommittee to keep working on the matters with which it has been concerned and report again at later meetings.

Bureau of Information.—Dr. West reported that the Bureau of Information is going ahead with the accumulation of information and has recently taken on some work incident to the activities of the Committee on Rural Medical Service. He stated that there is great desire on the part of farm organizations to make contacts with state and county medical societies to work out some plan for medical service in rural areas, and that the representatives of the farm organizations are very intelligent and sincere people. It occurred to Dr. West that the Committee on Postwar Medical Service might become a part of the picture. He said that the records as they were being developed in the Bureau of Information for a while seemed to encourage the hope that a number of men—more than expected—would be willing to settle in rural areas, but the proportion as evidenced by more complete data is gradually dwindling.

The number of visits to the Bureau from returning medical officers has greatly decreased, but it is anticipated that it soon will increase again. The Bureau is trying to be as helpful as possible in every respect. The correspondence coming to the Bureau contains many complaints from men who feel they are being unduly kept in service with nothing to do, some insisting that they never have had anything to do. Some of the complaints appear to be justified, but there is nothing that the Bureau of Information can do about this, and Dr. West felt sure that the Surgeon Generals of the Army and Navy have done and are doing all they possibly can to clear up the very complicated situation. It is probable that the Bureau of Information will be continued after this emergency for the purposes of the American Medical Association itself to gather information and data which can be used to advantage.

Father Schwitalla discussed the matter of rural medical service, saying that the Catholic Rural Life Conference had accomplished a great deal in getting people settled in rural areas and back on the farms. He also said that on the question of medical service in rural areas the people ask why it is that they cannot get a physician when they promise funds "and everything"; that the funds are there and hospitals have been erected, and still not enough doctors will settle in some places.

Dr. West stated that his impressions were slowly crystallizing into an opinion that one of the chief reasons why physicians cannot be retained in strictly rural areas is the lack of social and cultural contacts of the kind they most desire. Another phase of the matter, he said, is that some physicians go into country practice under contract with the provision that they can do all the private practice they wish but have no time for private practice.

Father Schwitalla asserted that one complaint of the farm groups is that they do not get any cooperation from the local medical and hospital groups. Dr. West mentioned that several of the state medical societies having medical service plans are trying to extend their service into rural areas.

After further discussion it was moved, duly seconded and carried that a representative of the Committee on Rural Medical Service be made a member of the Committee on Postwar Medical Service. (On request of the Chairman, Dr. F. S. Crockett of Indiana, Chairman of the Committee on Rural Medical Service, has accepted membership.)

Dr. Bierring mentioned as an important feature of the hospital construction measure—the Hill-Burton—the fact that the disposition of funds is going to be dependent on a careful survey in each state by local people, who will determine the need and whether future maintenance will be assured.

The Chairman said he would ask for a further progress report at the next meeting.

Veterans Administration.—Father Schwitalla, Chairman of the Subcommittee to Confer and Cooperate with the Veterans Administration, reported that he and Dr. Johnson, with Mr. Russ Clark of the American Hospital Association, had had another satisfactory conference with representatives of the Veterans Administration. Dr. Johnson had drawn up a statement for publication in The Journal which the Subcommittee had hoped by this time would have received approval from the Veterans Administration so that it might be released to The Journal at once but, although Mr. Stirling in a phone conversation had indicated that approval would be forthcoming immediately, it had not yet been received, and the Subcommittee was not in position, until receipt of such approval, to make any recommendation to the Committee.

The Chair entertained a motion, which was adopted, authorizing publication of the Subcommittee's report as soon as it becomes available. (Note.—The report of the Subcommittee was published in The Journal, January 26, pp. 216-218.)

The Chairman presented a letter addressed to the Committee on Postwar Medical Service and signed by eleven Army medical officers on duty with the Veterans Administration. The letter was in the nature of a protest against the inclusion of osteopaths in the Veterans Administration bill, H. R. 4717.

A telegram presenting a similar protest from officers at Bay Pines, Fla., was presented, and the Committee was informed that that communication had been forwarded to the Administrator of Veterans' Affairs in Washington.

There was extended discussion concerning various problems of the veteran medical officers, including the matter of payment by hospitals to residents, the adequacy or inadequacy of the stipend allowed hospital residents under the G. I. bill and the lack of facilities in and increased expense to hospitals that are trying to provide more residencies than normally. In reply to a question by Dr. Kirklin, Dr. Johnson stated that there still was a distinct shortage of residencies and that the shortage probably would increase during the next few months.

It appeared to be the consensus that all residents in hospitals should receive the usual stipends, and that whatever could be accomplished in the way of increasing subsistence payments allowed under the educational provisions of the G. I. bill should be attempted.

The Chairman stated that the Subcommittee was authorized to proceed and announced the addition to its membership of Mr. J. W. Holloway Jr., Director of the Bureau of Legal Medicine and Legislation of the American Medical Association.

Licensure.—Dr. Bierring referred to action taken by the Executive Committee of the Federation of State Medical Boards recommending "That the federation reaffirm its disapproval of admitting to licensure returning medical officers who are graduates of unapproved medical schools, except in those states where special licensure provision is made for such graduates." Another action of the Executive Committee, to be submitted to the federation for final approval, was "That the federation recommend to the member state boards and the District of Columbia requiring medical licensure for hospital residents a reconsideration and clarification of the purposes of hospital residencies as an educational feature, this to apply particularly to returning medical officers. If considered as a part of postgraduate training, that the duties of such positions be clearly defined in order to permit exemption from medical licensure."

A motion was adopted to appoint a subcommittee whose duty it would be to look into the matter of licensure of residents and of the refusal in some areas of county medical societies to take into membership without a probation period of anywhere from one to three years those medical veterans who move into their communities, sometimes on the advice of the Procurement and Assignment Service, and try to set up a practice.

The Chairman appointed the following subcommittee to look into these questions and report: Dr. Morris Fishbein, Chairman; Dr. Victor Johnson; Mr. J. W. Holloway Jr.

Mr. Davis summarized the situation in Michigan with respect to the licensure of residents. He stated that the licensing law in Michigan was passed in 1898 and there is nothing in it about licensing residents; that resident licensure was purely a regulation of the state licensing board, and that the attorney general of the state seems to have been finally convinced that there is nothing in the Michigan law to support it. He thought Dr. Bierring might look into various state laws and thus learn that the requirement of a license from residents in most if not in all of the states requiring them has been done under regulations of the licensing boards rather than under the law itself. Mr. Holloway said that as long as regulations are not in conflict with the actual law they have the complete effect of law, and he questioned the authority of a state board to exempt from license a resident who may be going to engage in the practice of medicine.

After further discussion hinging on the question of the returning medical officer who takes up a residency as a means of refreshing his medical knowledge being forced to pay a resident license fee, the Chairman requested Dr. Bierring to follow up the problem and report at the next meeting.

Assistance to the Philippines.—The Chairman asked for comments from the Committee members and for ideas as to anything further that might be done in the matter of rendering aid to the medical profession in the Philippines, mentioning the report made by Dr. James E. Paullin at the December meeting of the Committee.

General Lull stated that a number of Philippine physicians are being sent to this country for training—about fifteen physicians from the Philippine army.

New Business.—The Chairman brought to the attention of the Committee several communications from medical officers still in service, both in the Army and in the Navy, complaining because of their prolonged and, to them, unnecessary retention in the armed forces. Captain Eaton said that the Navy officers still on duty outside the United States were beyond the jurisdiction of the Bureau of Medicine and Surgery, and the Surgeon General can do nothing about those now in the Pacific; that the men were being relieved just as fast as possible; that it is to be remembered that the Medical Corps of the Navy had expanded from a small number to a host, and that the number in the regular Medical Corps is absolutely inadequate to staff the Navy's own hospitals. Colonel Piper informed the Committee that, on Jan. 3, 1946, 20,483 medical officers had been discharged from the Army and 29,640 nurses from the Army Nurse Corps. General Lull stated that, in the European Theater of Operations, when a man is declared surplus he is sent to a port and as soon as he is at the port he is crossed off the ETO books, but nothing can be done for the men in the Pacific.

Actions of House of Delegates of American Medical Association.—It was reported by the Chairman that the report of the Committee on Postwar Medical Service presented to the House of Delegates of the American Medical Association at its meeting in December had received the approval and appreciation of the House, which expressed the hope that the Committee would be continued. He stated that the work of the Bureau of Information also had received commendation, and expression had been given to a hope that the Bureau might be continued and probably placed on a permanent basis.

The Chairman further informed the Committee that the House of Delegates had authorized the appointment of a Committee on Military Medical Service whose purpose it would be to look into the question of how military medical service might be aided in the postwar period and in the event of hostilities in coming years, and to evaluate military medical activities in the war just ended with the hope of creating an acceptable plan for the setting up of a military medical establishment in future emergencies which would avoid mistakes made in the recent past. He said that the new committee would be appointed by the Board of Trustees in February and the Committee on Postwar Medical Service would be informed.

Remarks of Liaison Members.—Father Schwitalla brought up the question of the future scope of the Committee on Postwar Medical Service, saying that if it turns out to be a committee of the postwar period not necessarily having a tie up with the war, other matters of immediate and important interest to the profession could be considered; that the Committee as now constituted with representatives of so many important medical organizations could become a valuable medium for the interchange of opinion among the various organizations represented, and that future objectives merited further definition.

The Chairman stated that the Committee had considerable unfinished business with which it could well deal, and that a little later the desirability of extending or changing its scope along the lines suggested by Father Schwitalla might be considered and recommendations made to the groups represented on the Committee. He said that it might be desirable to have a number of organizations sitting around one table considering the problems of American medicine, as had been the case during the existence of the Committee on Postwar Medical Service.

Colonel Wergeland discussed the Army's refresher program for returning veterans, stating that authority has now been received from the War Department providing for three months refresher courses, which will take some of the load off veterans' hospitals. He pointed out that medical officers cannot be recalled from terminal leave for this purpose. They may now sign up for three months work in any hospital.

Time and Place of Next Meeting.—It was decided to hold the next meeting of the Committee at American Medical Association Headquarters, Chicago, March 9, 1946.

Medical Legislation

MEDICAL BILLS IN CONGRESS

National Mental Health Act

H. R. 4512 passed the House, March 15, proposing to amend the Public Health Service Act to provide for research relating to psychiatric disorders and to aid in the development of more effective methods of prevention, diagnosis and treatment of such disorders. This bill would make available to the Public Health Service annually the sum of $10,000,000 to carry out its purposes and an additional appropriation of $4,500,000 to construct a National Institute of Mental Health in or near the District of Columbia.

Hill-Burton Hospital Construction Bill

The Public Health Subcommittee of the House Committee on Interstate and Foreign Commerce has concluded hearings on S. 191, the Hill-Burton hospital construction bill. Representatives of the Association appeared before the subcommittee on March 8 in support of the general objectives of the bill. Congressman Priest, chairman of the subcommittee, has indicated that committee action on the bill will be expedited as much as possible.

Army Chiropody Corps

Congressman Traynor, Delaware, has introduced H. R. 5761, a bill to establish a Chiropody Corps in the Medical Department of the Army, to consist of sixty commissioned officers in grades from colonel to second lieutenant inclusive. The bill is pending in the House Committee on Military Affairs, of which Congressman May, Kentucky, is chairman.

Veterans Administration

H. R. 5638, introduced by Representative Havenner, California, proposes to authorize an appropriation of $900,000 to construct a 150 bed patient capacity addition to the existing Veterans Administration facility, Fort Miley, California, for the treatment of general medical and surgical disabilities.

H. R. 5574 has been favorably reported by the House Committee on World War Veterans' Legislation, proposing to increase from $500,000 to $1,500,000 the revolving fund available for loans to disabled veterans pursuing vocational rehabilitation.

STATE LEGISLATION

California

Bill Enacted.—A. 61-X has become chapter 87 of the Laws of 1946. It provides an appropriation of $4,000,000 to the regents of the University of California for the purpose of additional construction, improvements and equipment for the Medical Center of the University of California at San Francisco.

Kentucky

Bills Introduced.—H. 300, to amend the law relating to pharmacies and drugs, proposes to make it unlawful to sell at retail any drug which contains any quantity of aminopyrine, barbituric acid, cinchophen, dinitrophenol, pituitary, sulfanilamide, thallium acetate, thyroid, or their derivatives, or a drug or device the label of which bears a statement that it is to be dispensed or sold only by or on the prescription of a physician, dentist or veterinarian, unless such drug is sold on a written prescription signed by a member of the medical, dental or veterinary profession who is licensed by law to administer such drug or device, and its label bears the name and place of business of the seller, the serial number and date of such prescription, and the name of such member of the medical, dental or veterinary profession. S. 251, relating to licenses to practice certain professions, proposes that any person serving in the armed forces who, at the time of entering such service, was licensed to practice a profession in any other state by the proper authority of such state and who, at the time of entering the service, would have been entitled to receive without examination a license to practice such profession in Kentucky under any statute of Kentucky authorizing the issuance of reciprocal licenses, shall, on making application within one year after being separated from the service, be entitled to receive without an examination a license to practice such profession in Kentucky, notwithstanding that since the time of entering such service the state in which he was licensed to practice has ceased to issue licenses to practice such profession on a reciprocal basis. S. 252, relating to medical scholarships, proposes to authorize the state board of health to establish annual medical scholarships of the annual value of $800 each. The proposal would require an applicant to sign a written contract under the terms of which he agrees to pursue the medical course of an accredited medical college located within Kentucky until his graduation and to complete a term of not exceeding two years as an intern at some approved hospital to engage continuously in the general practice of medicine in a rural community in Kentucky selected by the state board of health for a period of years equal in number to the years that he shall be a beneficiary of such scholarship.

Bills Passed.—H. 171 passed the house March 6. It proposes the enactment of a law authorizing the establishment, maintenance and operation of medical service plan corporations. "Medical services" would mean the "general and usual services rendered and care administered by doctors of medicine." "Participating physician" would mean a "doctor of medicine licensed to practice medicine and surgery in this state under the provisions of the medical practice act" who agrees in writing to perform the services specified by the subscription certificates. S. 87 passed the senate March 14. It proposes that no person after July 1, 1946 shall maintain a hospital in the state without first obtaining a license therefor. The word hospital is defined as "any institution which maintains and operates organized facilities for the diagnosis, treatment and care of human beings suffering from illness, injury or deformity, where bedside nursing care is rendered for a period exceeding twenty-four hours, to care for 10 patients or more." S. 109 passed the house March 12. To amend the law relating to the practice of chiropractic, it increases the required period of academic training and adds philosophy to the list of subjects which must be studied.

Bills Enacted.—H. 257 was approved March 6, 1946. To amend the law relating to divorce, it authorizes the granting of a divorce when one spouse has become permanently and incurably insane and has been confined in an asylum for at least five years prior to filing the suit. In such action the court shall find from the testimony of two or more physicians competent in psychiatry that such insanity is permanently incurable.

Massachusetts

Bills Introduced.—S. 426 proposes to authorize the department of public health to construct an 800 bed hospital for the care of persons suffering from chronic diseases. S. 427 proposes to authorize the department of public health to continue its program for the production and utilization of blood plasma and other products derived from blood.

Bill Passed.—H. 74 passed the senate March 12. To amend the law relating to bacteriologic laboratories, it proposes to authorize the department of public health to grant certificates of approval for laboratory tests on milk, foods, eating utensils, water and sewage in accordance with such rules and regulations as the department may establish.

Mississippi

Bill Introduced.—H. 745, to amend the law relating to divorce, proposes to authorize the granting of a divorce on the grounds of insanity after a thorough examination of such insane person by three physicians who are recognized authorities on mental diseases and who agree that such insane person is incurable.

Bills Passed.—H. 782 passed the house March 13. It proposes that any person who has been in any branch of the armed forces of the United States, who has a license to practice any profession in Mississippi and who is required by law to pay dues to any licensing board or association shall be exempt from the payment of such dues for the time while he is in the service of his country and shall be reinstated as a member in good standing without payment of any back dues. S. 155 passed the senate March 12. To amend the law relating to the licensing of nurses, it proposes certain standards which a hospital must maintain in order to be recognized and approved as a training school for nurses.

Missouri

Bill Introduced.—S. 456 proposes the creation of a division of the state department of education to be known as the division of registration and examination and assigns as boards of said division the state board of medical examiners, state board of osteopathic registration and examination, state board of chiropractic examiners and others.

Bills Passed.—S. 359 passed the senate March 5. It proposes the establishment within the department of education of a division of registration and examination to coordinate the work of existing boards of registration and examination, including the state board of medical examiners, the state board of chiropractic examiners and the state board of osteopathic registration and examination. S. 424 passed the senate March 12. It proposes to transfer to the state board of medical examiners certain powers and duties heretofore vested in the state board of health. S. 435 passed the senate March 5. It proposes to transfer to the executive secretary of the division of registration and examination of the state department of education certain powers heretofore vested in the state board of chiropractic.

New Jersey

Bill Introduced.—A. 418, to amend the workmen's compensation act, proposes to provide proper workmen's compensation in cases of hernia.

Bills Passed.—A. 69 passed the senate March 11. It proposes to authorize the establishment and maintenance of blood banks to collect, process, store and distribute human blood and the various human blood derivatives, including special therapeutic and diagnostic serums which are deemed of value in the treatment of sick and injured persons, and the prevention of certain diseases. A. 147 passed the assembly March 12. It proposes that the holder of a license to practice a profession the license or registration certificate of which was forfeited or lapsed because of the passage of time while the holder thereof was in the armed forces shall be entitled, without examination or reexamination, within six months after his discharge, to a renewal or reinstatement of such license on payment of the lawful fee.

New York

Bills Introduced.—A. 2087 is similar to S. 1572 previously reported. It proposes the creation of a board of massage examiners and defines massage as "treating the human body for hygienic or remedial purposes by stroking, kneading, tapping or rolling with the hands or with other instrumentalities for the purpose of relieving, alleviating or reducing affected parts thereof but shall not include reduction of a fracture or dislocation of a bone." A. 2104 proposes the creation of a state board of chiropractic examiners and defines the practice of chiropractic as "the science of locating and the removing of nerve interference in the human body, according to chiropractic principles, where such interference is indicated; or misalinement; or subluxations of the vertebral column appear. It excludes operative surgery, the reduction of fractures, the prescription or use of drugs or medicine, and the practice of obstetrics." A. 2121 is similar to S. 1626, previously reported. It proposes the creation of a board of nutrition control at least one member of which shall be a licensed doctor of medicine, to adopt and specify standards of quantity, quality and character of food to be fed to all wards, inmates and patients in all institutions of the state except those in the department of education. A. 2165 is similar to S. 1797, previously reported. It proposes that physician members of the industrial council shall not be eligible for authorization to render medical care under this chapter and shall not examine, treat, consult or in any other way care for a compensation claimant at the request either of such claimant or of a carrier. A. 2206 is similar to S. 1904, previously reported. It proposes the creation of a temporary state commission to make an intensive study and survey of social, educational and physical problems of individuals afflicted with cerebral palsy with the view and for the purpose of devising and recommending a program for the aid, care, treatment and rehabilitation of such persons. The proposal would require at least two members of the commission to be physicians or neurologists of conceded eminence, with especial knowledge of the causes and effects of cerebral palsy and the treatment and care of persons suffering therefrom. A. 2366, to amend the public health law, proposes to make it the duty of every householder, before employing any person for domestic service in his household, to require from such person the production and surrender of a certificate of good health from a duly licensed and registered physician, issued not more than thirty days prior to the date of application or commencement of such employment, certifying that such person is free from tuberculosis, any venereal disease in its communicable or infectious stage or any other infectious, contagious or communicable disease. The employee would be required to be reexamined each six months. A. 2377 proposes to authorize corporations organized under the consumers' cooperative stock corporation law for the purpose of furnishing medical expense indemnity service to persons who become subscribers under contracts with such corporations to reincorporate under the membership corporations law. A. 2395, relating to the creation of a nutrition council, proposes the creation of a state nutrition council to coordinate all of the state's nutritional activities, conduct research or allocate a portion of its funds for research in nutrition; recommend reorganization of the state's nutritional activities; launch a widescale advertising, publicity and promotional campaign of instruction of the elements constituting a sound diet and the proper use of such farm products as may become surplus from time to time; and to do such other things as the council may deem essential for improving the nutritional status of the people. S. 1857 is similar to A. 2140, previously reported. It proposes to authorize qualified dentists or qualified dental assistants to use general anesthetics in the care and treatment of dental patients but would require such persons to have at their disposal at the time of administering any general anesthesia the necessary drugs, medicines and equipment for resuscitation as the board of dental examiners shall prescribe. The qualified dentist or dental assistant is defined as one who has passed an approved course of training or who has approved experience in the administering of anesthetics. S. 1955 is similar to A. 2157, previously reported. To amend the workmen's compensation law, it proposes that medical services shall include roentgenology, physical therapy, pathology and anesthesiology. S. 2038, to amend the labor law, proposes the enactment of a disability benefit law. S. 2218 proposes an appropriation for the use of the memorial cancer center fund for cancer research and for the treatment, prevention and cure of cancer and allied diseases. S. 2238, to amend the insurance law, proposes to remove therefrom the general prohibition against authorizing foreign or alien medical expense indemnity or hospital service corporations from doing business in the state. S. 2260 proposes the creation of a temporary state commission to make a study and survey of the prevalence and facilities for the treatment of cancer cases within the state. S. 2292, to amend the education law, proposes a new section dealing with license by endorsement. The proposal would authorize the endorsement of the diploma and license of a physician from another state, and the issuance of a reciprocal license to practice medicine and surgery in New York to such physician, if he shows that he is a citizen of the United States, is not less than 35 years of age, has a degree of doctor of medicine from a class A school in the United States, Canada or foreign medical school, has secured a license to practice medicine and surgery from any state in the United States after written examination, has honorably served not less than three years as a permanently or temporarily commissioned officer in the medical corps of the United States Army or Navy during World War I or II and has obtained both the diploma and license to be endorsed at least one year prior to entry into the armed forces as a permanently or temporarily commissioned medical officer.

Bills Passed.—A. 1249 passed the assembly March 11 and the senate March 13. To amend the law relating to the practice of osteopathy, it proposes that persons holding a license to practice osteopathy who have been granted the additional rights provided for under existing statutes and persons who shall meet all the preliminary and professional requirements required as of Sept. 1, 1936 and have satisfactorily passed or shall satisfactorily pass the regular medical licensing examination shall be granted the right to practice medicine without limitation as defined by the statutes of the state of New York. S. 556 passed the assembly March 12. To amend the law in relation to hospital liens, it proposes that such liens shall not include personal services rendered by a physician or surgeon and that the rates charged by the hospital shall be deemed equivalent to the scheduled rates currently approved by the industrial commissioner and the superintendent of insurance for cases under the workmen's compensation law. S. 1000 passed the senate March 11. To amend the law relating to privileged communications, it proposes the waiver of such privilege by any party in interest in any litigation wherein the interests of the personal representative of the deceased patient are deemed by the trial judge to be adverse to those of the estate.

Rhode Island

Bills Introduced.—H. 771 proposes an appropriation to the state department of health to carry on an experimental dental research study in administrative practice in conjunction with the United States Public Health Service. H. 789 proposes to authorize any person arrested by the police of any city or town in the state or by a member of the state police to have the right immediately after his arrest to use a telephone in order to get in touch with his physician, his attorney or a member of his family. H. 828 proposes that no person, firm or corporation shall dispense benzedrine except on receipt of an original nonrefillable prescription therefor. S. 141 proposes to authorize the governor to appoint a special blood plasma bank commission to study the feasibility of establishing blood plasma banks in the several counties of the state, free for all who need it in the judgment of their doctors.

Virginia

Bills Passed.—H. 257 passed the senate March 9. It proposes that any person who has tuberculosis in a communicable form who, having been instructed in writing by the local board of health, department of health or health officer or superintendent of any sanatorium of the state to take precautions to protect the members of his household and the public from being infected by tuberculosis communicated by such person, wilfully refuses to follow such instructions shall be guilty of a misdemeanor. H. 378 passed the senate March 6. It proposes regulations for the creation of local hospital or health center commissions. S. 21 passed the house March 9. It proposes that the state board of health be authorized to initiate and administer a program of hospital treatment and care for indigent persons residing in the state. S. 237 passed the house March 7. It proposes the creation of an examining board for the certification of clinical psychologists.

Bills Enacted.—S. J. R. 20 was adopted March 6. It provides for the creation of a commission to make a thorough and complete study of problems related to hospital and medical care, including the need of hospitals and health centers in the state, adequate plans for the prepayment of hospital and medical care for all classes of citizens, with due emphasis on the special needs of rural people, and other items related to the health and medical care of the citizens of the state. S. 166 has become chapter 119 of the Laws of 1946. It amends the law relating to hypnotic drugs by redefining the words "dangerous drugs" so as to include, in addition to preparations already so included, "Hormones, or hormone drug preparations, whether of natural origin, prepared from the so-called glands of internal secretion or endocrine glands, or whether synthetically produced, by whatsoever trade name or designation, or any compound or mixture thereof; except preparations intended for external use containing hormones in combination with other ingredients unfit for internal administration." Under this law no person will be able to sell or give away any such drug except on the prescription of a doctor of medicine, doctor of osteopathy, doctor of dental surgery or doctor of veterinary surgery, lawfully practicing his profession, and prescriptions for hormones can be refilled only the number of times specified on the face of the prescription by the prescriber.

Washington Letter

(From a Special Correspondent)

March 18, 1946.

Delay of Truman Health and Medical Care Program

Congress has not yet acted finally on President Truman's proposed health and medical care program and many other projects which he stated were must legislation. Most of his legislative recommendations, some almost a year old, are in the Congressional mill, but few have emerged as law. His request for fair employment practices legislation was shelved, his labor and employment bills were scaled down The only administration items to go through pretty much as asked were surplus disposal measures Hearings have been under way on extension of price control and war powers and the British loan. Still awaiting final action are the health and medical care program, extension of the Selective Service act beyond May 15, the increased legal minimum wage, a comprehensive program for scientific research, the universal training program, the Presidential succession, the use and control of atomic energy, strategic materials stockpiling and social security coverage for veterans during military service.

Negro Doctors to Serve in Veterans' Hospitals

Dr. Paul R. Hawley, Veterans Administration medical director, reports that the way has been cleared for appointment of Negro doctors in veterans' hospitals, with local custom to be the ruling factor in appointments. He is considering plans to set up all Negro units in a number of hospitals with Negro patients to be attended by Negro doctors and nurses. Dr. Hawley reports that 152 full time resident physicians are now on duty in eight veterans' hospitals. The House Military Affairs Committee has voted favorably on a bill to permit retired officers to work as physicians, executives and hospital managers for the Veterans Administration without affecting their retired status.

President Given Control of Atom by Senate Group

The Senate Atom Energy Committee has voted to give the President direct control over production of atom bombs and other military applications of nuclear energy. Under the pending control bill a five man civilian commission would be authorized to produce atom weapons on "express consent and direction of the President." Mr Truman told a recent press conference that he was determined that atomic energy control should remain in civilian hands. He denied that military control of nuclear development was needed for national defense, declaring that as Commander in Chief he was charged with responsibility for the security of the nation.

Senate Action Expected on Mental Health Bill

Senator Claud Pepper, Democrat of Florida, expects early Senate action on the bill to establish a mental health institute in Washington, which was approved by the House by a standing vote of 74 to 10. Sponsored by Representative Priest, Democrat of Tennessee, who was supported by Representative Brown, Republican of Ohio, in piloting the bill through the House, the bill would appropriate $4,500,000 for a psychiatric research institute at Bethesda and would authorize $10,000,000 annually for research seeking cures for mental disorders

Nurses' Memorials Wanted Outside Washington

In addition to the $2,000,000 home for nurses planned for Washington as a national memorial to their work in the war, memorials in other cities have been requested. Arthur H. Johnson, chairman of a committee planning to raise funds for the Washington memorial, said that dwelling places for nurses are desired in other sections of the country "Once the main objective, a social center and dwelling place for war nurses in the nation's capital, is reached, we will decide on location of other centers"

Amputees Ask Government to Supply Automobiles

Three hundred war amputees met at Forest Glen Hospital to endorse a letter to President Truman asking that the government provide them each with a car in an attempt to remove their handicap in industrial competition

Official Notes

PIONEER TELEVISION PROGRAMS BY A. M. A.

The Bureau of Health Education announces a series of experimental telecasts over television station W9XBK, Chicago, beginning April 2 and running for twenty-six weeks

The following subjects will be shown:

April 2 —Evolution of the stethoscope. Dr Edwin P Jordan.
April 11.—Medical uses of the x rays Mr H A. Carter
April 25 —The basal metabolic rate Dr. William W Bolton
May 9 —Blood examinations Dr J J. Moore.
May 23 —Blood pressure demonstration Dr. William W. Bolton
June 6 —Contagious disease precautions in the home Dr W. W. Bauer.
June 20 —Methods of administering drugs Dr Austin E Smith

The programs are being telecast on a sustaining basis; that is, the station will derive no revenue. Credit will be given on the program to Chicago medical supply firms which lend apparatus for demonstration, but there will be no other advertising. Scripts will be prepared in cooperation with each medical demonstrator and coordinated by the Bureau of Health Education Dr. W. W. Bauer will summarize the odd numbered programs and Dr. William W. Bolton the even numbered programs.

Coming Medical Meetings

Aero Medical Association, Chicago, April 7 9. Dr. David S. Brachman, 1016 Dime Building, Detroit 26, Secretary.

Alabama, Medical Association of the State of, Birmingham, April 16 18. Dr. Douglas L Cannon, 519 Dexter Ave, Montgomery 4, Secretary.

American Association of Anatomists, Cleveland, April 4 6 Dr. Eliot R. Clark, University of Pennsylvania School of Medicine, Philadelphia 4, Secretary

American College of Physicians, Philadelphia, May 13 17. Mr. E. R. Loveland, 4200 Pine St., Philadelphia 4, Executive Secretary.

American Pediatric Society, Skytop, Pa, May 1 3 Dr. Hugh McCulloch, 325 N. Euclid Ave, St Louis 8, Secretary.

American Society for Research in Psychosomatic Problems, New York, May 11 12. Dr. Edwin G Zabriskie, 714 Madison Ave, New York 21, Secretary.

American Surgical Association, Hot Springs, Va, April 2 4 Dr. Warfield M Firor, Johns Hopkins Hospital, Baltimore 5, Secretary.

Arizona State Medical Association, Phoenix, May 2 3. Dr. Frank J. Milloy, 112 N. Central Ave., Phoenix, Secretary.

Arkansas Medical Society, Little Rock, April 14 15. Dr. W. R. Brooksher, 602 Garrison Ave, Fort Smith, Secretary.

California Medical Association, Los Angeles, May 7 10. Dr. George H. Kress, 450 Sutter St, San Francisco 8, Secretary.

Central States Dermatological Society, Detroit, April 27. Dr. Clarence E Reyner, Henry Ford Hospital, Detroit, Secretary.

Connecticut State Medical Society, Hartford, May 1 3. Dr. Creighton Barker, 258 Church St, New Haven 10, Secretary

Florida Medical Association, Jacksonville, April 22 24 Dr. Robert B McIver, P. O. Box 1018, Jacksonville, Secretary.

Georgia, Medical Association of, Macon, May 7 10. Dr. Edgar D. Shanks, 478 Peachtree St, N E, Atlanta, Secretary.

Illinois State Medical Society, Chicago, May 14 16. Dr. Harold M. Camp, 224 S. Main St, Monmouth, Secretary.

Iowa State Medical Society, Des Moines, April 17 19. Dr. John C. Parsons, 406 Sixth Ave, Des Moines 9, Secretary

Kansas Medical Society, Wichita, April 22 25 Dr F. R. Croson, 112 W. Sixth St, Topeka, Secretary

Louisiana State Medical Society, Alexandria, May 6 8 Dr P. T. Talbot, 1430 Tulane Ave, New Orleans 13, Secretary

Maryland, Medical and Chirurgical Faculty of, Baltimore, April 23 24. Dr W. Houston Toulson, 1211 Cathedral St, Baltimore 29, Secretary.

Mississippi State Medical Association, Jackson, May 14 15 Dr T M. Dye, Box 295, Clarksdale, Secretary.

Missouri State Medical Association St Louis, March 24 26 Dr Ralph L Thompson, 634 N Grand Blvd, St Louis 3, Secretary

Nebraska State Medical Association, Lincoln, May 6 9 Dr R B Adams, 416 Federal Securities Bldg, Lincoln 8, Secretary.

New Hampshire Medical Society, Manchester, May 14 Dr C R. Metcalf, 5 S State St, Concord, Secretary

New Orleans Graduate Medical Assembly, New Orleans, April 1 4. Dr Joseph S D'Antoni, 1430 Tulane Ave, New Orleans 13, Secretary.

New York, Medical Society of the State of, New York, April 29 May 3. Dr Walter P. Anderton, 292 Madison Ave, New York 17, Secretary.

North Carolina, Medical Society of the State of, Pinehurst, May 1 3 Dr Roscoe D McMillan, P O Box 232, Red Springs, Secretary.

Northern Tri State Medical Association, South Bend, Ind, April 9 Dr John L Stifel, 232 Michigan St, Toledo 2, Secretary.

Ohio State Medical Association, Columbus, May 7 9 Mr. Charles S. Nelson, 79 E State St, Columbus Executive Secretary

Postgraduate Institute of the Philadelphia County Medical Society, Philadelphia, April 9 12 Dr George P. Muller, 301 S 21st St, Philadelphia, Director

Rhode Island Medical Society, Providence, May 15 16 Dr. William P. Buffum, 122 Waterman St, Providence 6, Secretary

South Carolina Medical Association, Greenville, April 30 May 2. Dr Julian P. Price, 105 W Cheves St, Florence, Secretary

Tennessee State Medical Association, Knoxville, April 9 11. Dr. W. M. Hardy, 706 Church Street, Nashville, Secretary

Texas, State Medical Association of, Galveston, May 6 9. Dr. Holman Taylor, 1404 W El Paso St, Fort Worth 3, Secretary.

West Virginia Medical Association, Huntington, May 13 15 Mr Charles Lively, P O Box 1031, Charleston 24, Executive Secretary.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Personal.—Dr. Claude F. Dixon, Rochester, Minn., was made an honorary member of the Los Angeles Surgical Society, February 8, at which time he discussed "Anterior Resection for Carcinoma of the Lower Sigmoid."

Diamond Jubilee.—On January 31 the Los Angeles County Medical Association held a dinner commemorating its seventy-fifth anniversary. As a feature of the occasion the bulletin of the society, January 31, was devoted to a complete review of the society's history, beginning with the meeting in 1871 of seven physicians in the office of Drs. John S. Griffin and Joseph P. Widney to organize the society. The preliminary meeting had been held on January 25. Dr. Widney is credited with being the founder of the School of Medicine of the University of Southern California, Los Angeles, of which he was first dean. The Diamond Jubilee issue of the bulletin contains interesting illustrations and discussions of the development of medicine in Los Angeles County.

COLORADO

Dr. Macomber Returns as Editor.—Dr. Douglas W. Macomber, Denver, has returned as editor of the Colorado State Medical Society. Dr. Lyman W. Mason, Denver, has been acting scientific editor while Dr. Macomber was serving in the army. Mr. Harvey T. Sethman has returned to his activities in the Colorado State Medical Society as executive secretary and managing editor of the *Rocky Mountain Medical Journal* (THE JOURNAL, Dec. 22, 1945, p. 1215).

CONNECTICUT

Conference on Pulmonary Diseases.—The Connecticut State Medical Society and the Veterans Administration are cooperating in the series of conferences the second of which was on pulmonary diseases, February 28. The speakers were:

Dr. James J. Hennessy, Hartford, Trends in Diagnosis and Treatment of Pulmonary Disease.
Dr. Joseph E. Dushane, Hartford, Pulmonary Disease in the Military Service.
Dr. Gustaf E. Lindskog, New Haven, Certain Aspects of Diagnosis and Treatment of Pulmonary Suppuration.
Capt. Morris Dressler, Newington, Pulmonary Disease with Relation to Heart Disease.
Dr. Joseph N. D'Esopo, New Haven, Thoracic Wounds in Battle Casualties.

Hospital Advisory Committee.—In anticipation of the passage of the Hill-Burton bill or similar federal legislation providing for studies of hospital and health center facilities in the states and grants to extend such facilities, Governor Raymond E. Baldwin has designated the state department of health as the official agency to act in this connection and named an advisory committee to the department to make the required studies. The committee, of which Dr. James R. Miller, Hartford, is chairman, is composed of twenty-six members representing health, hospital and nursing agencies, the state dental association and the Travelers Insurance Company. The committee held an organization meeting in Hartford on January 31.

Executive Director Named to Care for Inebriates.—With the appointment of Dudley P. Miller, Ph.D., as executive director of the Connecticut State Fund for Inebriates, a statewide system of free care for alcoholic addicts was launched January 25. Dr. Miller has been assistant director of New Haven Hospital and took over his new position March 15. The program will be financed by the fund to which will revert 9 per cent of all income from liquor license permits (THE JOURNAL, Dec. 1, 1945, p. 970). A board of trustees has been named for the fund, two physician members being Dr. Thomas P. Murdock, Meriden, formerly president of the Connecticut State Medical Society, and Dr. Arthur H. Jackson, Waterbury. Selden D. Bacon, Ph.D., of the department of sociology and the School of Alcohol Studies, Yale University, is chairman of the board. The program is said to be the first of its kind in the United States. It is planned to establish clinics in the major population areas and a number of convalescent centers for treatment of those who cannot be treated at home. The plans also call for a commitment center "to which courts and other constituted authorities may send for a period up to three years those inebriates for whom there is little or no hope of rehabilitation and who might otherwise be a liability and a danger to their communities." In a statement to the press, Dr. Bacon said the board would cooperate with the programs of Alcoholics Anonymous and the Yale school.

DISTRICT OF COLUMBIA

Group to Implement Compulsory Health Insurance.—*Medical Annals* reports that a group of physicians and laymen met at Pierce Hall January 26 "to set up a civic organization in Washington to carry on educational work for a national health program and to take any active legislative steps necessary to help implement that program, especially for compulsory health insurance." The group is further committed to support President Truman's national health program. Dr. Anna Tulman-Rand, chairman of the district chapter of the Physicians' Forum, called the conference and was elected chairman of the steering committee. Others who will serve on the committee are Dr. Irving W. Winik, Dr. Dorothy Boulding-Ferebee, Miss Margaret Stein, medical economist, Benjamin Asia of the district chapter of the National Lawyers' Guild and Rev. Francis W. McPeek of the Washington Federation of Churches.

ILLINOIS

Selective Service Personnel Honored.—The Congressional Medal of Merit was presented to 2,226 Cook County and Chicago members of the Illinois Selective Service system by Governor Dwight H. Green, January 23, at the Auditorium Theater, Chicago. The medal, authorized by Congress last July, was presented to local board members, appeal board members, government appeal agents, reemployment committeemen, physicians and dentists who have served the Selective Service System faithfully for a period of two or more years as of Nov. 30, 1945. In the case of a deceased member the medal was presented to a designated member of his family. Eligible members now serving in the military forces will receive their awards on release from service. Suitable ceremonies were held throughout the nation to honor Selective Service personnel in their respective states. In Illinois alone the honor group included at the time of this report 1,411 local board examining physicians, 388 physicians who were members of medical advisory boards, 18 physicians who were members of boards of appeal and 18 physicians who were members of local boards; 837 additional physicians who entered the armed forces while serving with the Illinois Selective Service System will receive the medal when they return to civilian life. Another group of 849 physicians have served or are serving the system but will not receive the medal by reason of their having resigned prior to the expiration of two years' service or by reason of having served less than two years.

Chicago

Solomon Memorial Foundation.—Dr. Joseph L. Wilkey was recently elected president of the Dr. Jerome D. Solomon Memorial Research Foundation, an affiliate of the Hektoen Institute of Medical Research, 629 South Wood Street, Chicago 12 (THE JOURNAL, Nov. 10, 1945, p. 756). The foundation research is sponsored by a medical advisory board consisting of Drs. Morris Fishbein, chairman, Ludvig Hektoen, Samuel J. Hoffman, Andrew C. Ivy, Raymond W. McNealy and Karl A. Meyer.

Loyola Will Not Close.—The current rumors that Loyola University School of Medicine intended to close are ended with announcement that the university is in the midst of discussions with the Medical Center Commission concerning space and position for the future Loyola medical school building. The medical school has been an integral part of Loyola University since 1915, when it came into being with the acquisition of Bennett Medical College, established in 1868, and the Chicago College of Medicine and Surgery. The medical school, which is approved by the Council on Medical Education and Hospitals of the American Medical Association, is located at 706 South Wolcott Avenue, the heart of the projected medical center area.

School for Handicapped Established.—The old North Chicago Hospital, 2551 North Clark Street, has been leased to house what will be known as the Illinois Children's Hospital School, a school for the handicapped, which was set up in recent legislation with an appropriation of $420,000 for the biennium ending June 30, 1947. Richard Eddy was appointed superintendent of the new project by Governor Dwight H. Green last October when he resigned as head of the Illinois State Training School for Boys, St. Charles. A medical program will be under the direction of Dr. Gerda B. Irving. Educational activities for children, who will range in age from 5 to 13 years, will be in charge of Miss Ruth A. Ryder, formerly educational and recreational supervisor in government hospitals in the Pacific War Theater. Miss Virginia Cornwell of Billings

Memorial Hospital was appointed director of occupational therapy. It is planned to open the school April 15 on an experimental basis, serving approximately 100 children of elementary age, to be taken from among those who are permanently handicapped, too crippled to attend regular school or who for various social reasons cannot study at home. The plan was evolved after a survey by the Illinois Commission for Handicapped Children, newspapers reported.

KENTUCKY

Personal.—Dr. Thomas P. Leonard has been named health officer of the city of Frankfort, a position he held prior to entering military service.——Dr. Philip H. Dorger was guest of honor at a dinner December 16 given in observance of his completion of twenty-five years as a member of the staff of the St. Elizabeth Hospital, Covington.

Girl Awarded First Scholarship Under New Fund.—Miss Juanita Phillips, Stearns High School teacher, is the first applicant to be accepted for a scholarship under the Kentucky Medical Scholarship Fund, newspapers report. Miss Phillips will receive a four year scholarship to the University of Louisville School of Medicine. The scholarship carries a loan of about $3,500 from the Kentucky Medical Scholarship Fund, set up by the Kentucky State Medical Association to provide medical facilities to make rural counties more attractive for practicing physicians and to enable students to complete their training. Miss Phillips, in accordance with the agreement, will, on receiving her M.D. degree and concluding her internship, return to McCreary County for four years for the practice of medicine. The scholarship fund was described in The Journal, January 19, page 162. The state legislature has been asked to set aside a revolving fund of $75,000 to help maintain the project.

LOUISIANA

Dr. Lapham Returns as Dean.—On January 1 Dr. Maxwell E. Lapham returned to his position as dean of Tulane University of Louisiana School of Medicine, New Orleans. Dr. Lapham had been in service with the navy.

Rudolph Matas Honored.—A gold plaque was presented to Dr. Rudolph Matas recently in honor of his completion of fifty years as a member of the staff of the Touro Infirmary, New Orleans. Dr. Matas, who is 85 years of age, graduated at Tulane University of Louisiana School of Medicine, New Orleans, in 1880.

Research Fund in Dermatology.— The Tulane University of Louisiana Medical School, New Orleans, has been left $100,000 by the late Dr. Henry E. Menage. The fund will be called the Henry E. and Henrietta Menage Research Fund in Dermatology and will be used for medical research on the causes, prevention and cure of diseases of the skin. Dr. Menage graduated at Tulane in 1892, receiving degrees in pharmacy and medicine. He joined the faculty in 1907 and later was made professor of dermatology. He was emeritus professor when he died in 1940.

MARYLAND

Alfred Blalock Declines Columbia Position.—Dr. Alfred Blalock, professor and head of the department of surgery, Johns Hopkins University School of Medicine, Baltimore, recently announced that he had declined an invitation to accept a similar position at Columbia University College of Physicians and Surgeons, and the Presbyterian Hospital, New York, it is reported.

MASSACHUSETTS

Tufts Alumni Meeting.—The annual dinner meeting of the Tufts Medical Alumni Association will be held at the Somerset Hotel, Boston, April 10, with Major Norman T. Kirk, Surgeon General of the Army, as guest speaker on "American Medicine in World War II." A message will be read from President Harry S. Truman. Other speakers will be Drs. Alonzo K. Paine, Reginald Fitz, Louis E. Phaneuf, Albert Warren Stearns, Dwight O'Hara, Benjamin Sachs, William E. Browne and Leonard Carmichael, LL.D., all of Boston. This year marks the fiftieth anniversary of the graduation in 1896 of the first class to complete the full program of studies as students of the Tufts College Medical School, Boston. A feature of the meeting will be the presentation to the medical school of a portrait of the seven founders of the medical school. The portrait is new and is a gift of the class of 1920. The subjects of the portrait are:

Dr. John W. Johnson, professor of obstetrics and gynecology.
Dr. Albert Nott, professor of physiology and dean.
Dr. Charles P. Thayer, professor of anatomy and secretary.
Dr. William R. Chipman, professor of surgery.
Dr. Henry W. Dudley, professor of pathology.
Dr. Frank G. Wheatley, professor of materia medica and therapeutics
Dr. Walter L. Hall, professor of medicine.

MICHIGAN

Inter-Professional Council.—Mr. William A. Freimuth of the Detroit Bar Association has been elected president of the newly organized Inter-Professional Council. The council was formed to develop a closer relationship between the professions and professional groups and to encourage friendly and constructive discussions between professions for mutual help and public service. Other officers are Dr. Willard D. Mayer, Wayne County Medical Society, vice president; Irett Ferris, Detroit Teachers Association, secretary, and Floyd Straith, Detroit District Dental Society, treasurer. Cooperating societies forming the membership of the new Inter-Professional Council include the Detroit Chapter of American Institute of Architects, Detroit Teachers Association, Detroit District Dental Society, Wayne County Medical Society, Michigan Association of Certified Public Accountants and the Engineering Society of Detroit.

Fund for Crippling Diseases.—On February 15 the council of the Wayne County Medical Society approved the program of the Fund for Crippling Diseases, a nonprofit organization devoted primarily to the study of rheumatic and allied diseases. The program is divided into three distinct sections: to raise funds by personal solicitation, to create an advisory research committee and to select and finance research projects. These three sections constitute the program to which this organization will devote its energies and funds. No further expansion of activities will be undertaken until such a time as the need for new activities is actually present and they are recommended by the local medical society and the American Rheumatism Association. All the solicitation for the raising of funds will be conducted by the present officers and trustees of the Fund for Crippling Diseases by personal contact. No solicitors will be employed and no fees or commissions will be paid. The advisory committee will be composed of nine members. At least six of the members will be medical doctors; the remainder will be Ph.D.s active in medical work. The board of trustees will dispense funds accumulated through solicitation, by gift or by grant to the projects recommended by the advisory committee in the amount and manner best suited to accomplish the results desired. All projects will be confined to local accredited schools and hospitals selected by the advisory committee. The new fund is a project developed from the proposed program of the Earl A. Peterman Foundation. In response to the request of Dr. Peterman, Detroit, for the society's approval, a special committee was appointed to study the plans. Since then the Earl A. Peterman Foundation has been incorporated under the name of the Fund for Crippling Diseases. Offices of the Fund for Crippling Diseases are Medical Director, 7600 John R Street, Detroit, and Research Division, General Offices, 19 Owen Avenue, Detroit. Dr. Earl A. Peterman is chairman of the board of trustees, Roy D. Potter, treasurer, and Joseph H. Conn is secretary. Plans call for a board of twelve trustees. Therefore nine more trustees will be elected to the board for three year terms; that is, three for one year, three for two years and three for three years and three year terms thereafter. The fund employs N. Chester Clark, 19 Owen Avenue, as full time business manager. The Earl A. Peterman Foundation identity is not being retained. The research advisory committee has not been formed as yet.

NEW YORK

Regional Hospital Council Formed.—The Council of Rochester Regional Hospitals has been established in a five year agreement with the Commonwealth Fund. Said to be the first of its kind in the country, the unit was established as an experimental plan to give rural hospitals the advantages of contact with the city medical center and opportunity to keep abreast of technics in use in city hospitals. Terms of a five year contract provide for an annual grant of $275,000 from the Commonwealth Fund, part of which will be used to establish an educational and consultative program for professional hospital personnel and part used for expansion of rural hospitals and purchase of additional hospital equipment if the need becomes apparent. Thomas R. White, president of the Rochester Hospital Council, was named president of the new council at an organization meeting February 26. The meeting climaxed almost a year's experimental program. The Rochester region was chosen by the Commonwealth Fund as the site of the experimental program after a study of a dozen or more areas possessing medical centers, such as that provided by Strong Memorial Hospital and the University of Rochester School of Medicine and Dentistry, it was stated. It is expected that other regional programs will be established on the lines of the one being set up in Rochester if the experiment proves successful. The council will name a director and will establish offices in the Reynolds Arcade Building. It will work in cooperation with the Rochester Hospital Council in developing the expanded program. A permanent program of educational activities will be set up by the council, including refresher courses and training in ward management and operating room and delivery room technic for graduate nurses and opportunities for exchange of experiences between hospital technicians, dietitians, medical record libraries and other staff members. A continuous postgraduate educational program for physicians will be organized which will embrace clinical conferences, short refresher courses and one to three year residencies and fellowships. An extensive clinical consultation service will be organized throughout the region. Cooperating hospitals, besides Rochester's six major hospitals and those in Canandaigua and Brockport, are Bath Memorial, Clifton Springs Sanitarium and Clinic, Dansville General, Bethesda and St. James Mercy in Hornell, Geneva General, and Soldiers and Sailors Memorial in Penn Yan.

New York City

Graduate Fortnight.—"Tumors" will be the theme of the nineteenth graduate fortnight of the New York Academy of Medicine, October 7-18.

Center for Persons Over Sixty-Five.—Representatives of social agencies and business groups of the East Side area are cooperating in the establishment of a recreational center for men and women more than 65 years of age. The objective of the center is to meet the problem of the aged by offering them an active environment with no intention of segregation.

Annie Goodrich Honored.—On February 26 a luncheon was held at the Waldorf Astoria Hotel to honor Annie W. Goodrich on her eightieth birthday. Miss Goodrich is credited with establishing the first graduate school of nursing at Yale University, New Haven, serving there as dean for eleven years as well as doing extensive pioneer work in the field of nursing.

The Menas Gregory Lecture.—Brig. Gen. William C. Menninger, director of the neuropsychiatric division of the Office of the Surgeon General, Army Service Forces, will deliver the second annual Menas S. Gregory Memorial Lecture at the New York University College of Medicine, April 26. His subject will be "Lessons from Military Psychiatry for Civilian Psychiatry."

Friday Afternoon Lectures.—The Medical Society of the County of Kings announces the following group of Friday afternoon lectures:

Dr. Irving J. Sands, Brooklyn, The Rehabilitation of the Neuropsychiatric Veterans, March 15.
Dr. Edwin K. Morgan, Brooklyn, Urologic Aids in General Practice, March 22.
Dr. John G. McNamara, Brooklyn, Orthopedics in Children, March 29.
Dr. Howard W. Potter, Brooklyn, Psychosomatic Medicine, April 5.
Dr. Henry W. Louria, Brooklyn, Practical Management of Diseases of the Thyroid Gland, April 12.

Colonel McEwen Returns as Dean.—Col. Currier McEwen, after more than two and a half years of military service, has resumed his duties as dean of the New York University College of Medicine. Granted a leave of absence by the university for military service, he entered active military duty May 6, 1943 and returned with the Bronze Star and the Legion of Merit. Col. McEwen first served as executive officer of the First General Hospital, which was the Bellevue affiliated unit. After training at Fort George G. Meade, Maryland, and Camp Pickett, Va., the unit sailed from Boston, Dec. 29, 1943, and opened as a functioning hospital at North Mymms Park, near London, Jan. 9, 1944, where for the first two months it experienced the Luftwaffe's "baby blitz" against London. In July 1945 Dr. McEwen joined the headquarters of the European Theater of Operations in Paris and Frankfort, Germany, as chief consultant in medicine.

Dr. Bernecker Resigns as Health Commissioner—Israel Weinstein Named.—Dr. Edward M. Bernecker on March 13 resigned as commissioner of health and was immediately reappointed to his former position as commissioner of hospitals. Lieut. Col. Israel Weinstein, newly appointed deputy commissioner of health, was appointed acting commissioner, pending the choice of a successor to Dr. Bernecker. At the same time the mayor accepted the resignation of William F. Jacobs, hospital commissioner, who took over that place on March 4, and approved his restoration to his former position of medical superintendent of Bellevue Hospital. Dr. David R. Rutstein, Albany, deputy commissioner of the New York City Department of Health since March 15, 1943, resigned, effective April 1. Dr. Rutstein has been in charge of social hygiene, child hygiene, nutrition and the Bureau of Tuberculosis. He was on the list of physicians recommended for the post of health commissioner to succeed Dr. Ernest L. Stebbins (THE JOURNAL, March 16, p. 727). On March 11 a resolution was adopted at a meeting of the committee on public health relations of the New York Academy of Medicine urging Mayor William F. O'Dwyer to rescind his recent action in the appointment of Dr. Edward M. Bernecker as health commissioner of New York City and to appoint as commissioner of health one who possesses the training and experience required by the city charter and who will maintain and extend high standards of public health in this city and, by example, throughout the nation. The resolution pointed out that the appointment of Dr. Bernecker is contrary to paragraph 551b of chapter 22 of the charter of the city of New York, which requires that the commissioner of health shall have had at least eight years' experience either in public health administration or teaching or both. These mandatory qualifications of the city charter are comparable to the training and experience required by the state of New York for health officers of all other cities in the state with a population of more than 50,000. In pointing out that Dr. Bernecker has not had the training or experience in public health administration or teaching required by the charter and therefore does not qualify under the law for the position of health commissioner of the city of New York, the academy has no intention of questioning his personal integrity or his qualifications as a hospital administrator. It wishes rather to indicate to the mayor that experience in hospital administration is in no way equivalent to that training or experience in modern public health practice which a health commissioner requires in arriving at important decisions daily which may affect the health of almost eight million people. The New York *Times*, March 13, reported that members of the board of health declared in a resolution that the appointment of Dr. Bernecker was contrary to the public interest and was "an unwarranted and unnecessary risk to the public safety." The *Times* carried a discussion of Mayor O'Dwyer's defense but indicated that he appeared upset at the actions of the board and the academy.

OHIO

Changes in Health Personnel.—Dr. Robert L. Thomas, Kinsman, was recently chosen health commissioner of Trumbull County, Dr. John A. Carter of the city of Middletown and Dr. Charles G. Goll, Stryker, of Williams County.——Dr. Nelson C. Dysart has resigned as health commissioner of Columbus.

Alpha Omega Alpha Lecture.—The annual address of the Alpha Omega Alpha Society of the University of Cincinnati College of Medicine was delivered by Dr. Herman J. Nimitz, Cincinnati, February 22. He spoke on "The Activities of the 25th General Hospital Unit in World War II." Dr. Nimitz was executive officer of this unit, which was composed of the medical and nursing staffs of the Cincinnati General Hospital and the medical school.

Harry Goldblatt Goes to California.—Dr. Harry Goldblatt has resigned as professor of experimental pathology and associate director of the Institute of Pathology at Western Reserve University School of Medicine, Cleveland, effective in August, to become director of an Institute for Medical Research being built for him at Cedars of Lebanon Hospital, Los Angeles. Dr. Goldblatt has been affiliated with the university since 1924. In 1932 he established the fact that high blood pressure can be caused by constriction of the renal artery, which reduces the blood supply to the kidneys.

Joint Committee on Tuberculosis Control Formed.—A joint committee on tuberculosis control has been organized in Ohio to develop a campaign for more adequate tuberculosis legislation in 1947. Dr. Carl A. Wilzbach, commissioner of health of Cincinnati, was appointed chairman of the committee. Seven state groups comprise the joint committee on a state level, and the campaign plans call for the formation of a similar committee in every county in the state within the next few months. The seven groups include the Ohio State Medical Association, the Ohio Conference of Tuberculosis Secretaries, the Ohio Public Health Association, the Ohio Federation of Public Health Officials, the Ohio Hospital Association, the Ohio Tuberculosis Hospital Association and the Ohio State Nurses Association.

TEXAS

Hospital Meeting.—The Texas Hospital Association is meeting at the Hotel Texas, Fort Worth, March 21-23. Holding concurrent sessions are representative groups of hospital administrators, medical record librarians, occupational therapists and woman's auxiliaries. The Texas Conference of the Catholic Hospital Association held a session March 20.

The Russ Endowment Fund.—Dr. and Mrs. Witten B. Russ, San Antonio, parents of the late Dr. Stirling Everett Russ, have given a $1,000 war bond to the Texas Memorial Library, the library of the State Medical Association of Texas, to establish the "Dr. Stirling E. Russ Endowment Fund." Only the interest from this fund, after the bond is matured and reinvested, will be expended in the development of the library, thus perpetuating the fund. Dr. Russ died at his home in San Antonio January 1.

Foundations Contribute to Medical College.—A section of the permanent building of the proposed Southwestern Medical College, to be built on Harry Hines Boulevard, will be known as the Braniff Research Laboratories, which was made possible through a recent $100,000 gift of the Braniff Foundation. The Braniff Foundation was established in 1943 for the purpose of advancing educational, charitable and religious institutions and to aid in the promotion of systems of scientific research. It is headed by Tom E. Braniff, president of Braniff Airways. The section provided by this fund will house the research work of Drs. Arthur Grollman, Warren B. Andrews, Tinsley R. Harrison and Simon Edward Sulkin, Ph.D., all of Dallas. The Hoblitzelle Foundation has given $125,000 to the Southwestern Medical Foundation to make possible the purchase of about 62 acres of land on Harry Hines Boulevard, on which the permanent buildings of Southwestern Medical College will be built. The land was given as a memorial to the late Mrs. Esther Thomas Hoblitzelle, wife of Karl Hoblitzelle, who founded the Hoblitzelle Foundation, which had its inception as a public welfare institution in December 1942. Serving with Umphrey Lee, Ph.D., Dallas, as trustees of the foundation are Judge Sara T. Hughes, Mrs. Earl H. Hulsey, Fred F. Florence and Karl Hoblitzelle. A suitable marker will be placed on the grounds of the college in honor of the late Mrs. Hoblitzelle.

WEST VIRGINIA

Register of Active Tuberculosis Cases.—The bureau of tuberculosis of the state health department has set up a register of all active cases reported to supplant its former records, which consisted of one set of files containing both active and inactive cases. At the time the original tuberculosis file was divided into active and inactive cases the inactive case cards were placed in a closed file, the active ones being placed on the register, furnishing the initial points at which some measure of control would be directed. At the cessation of tuberculosis activity case cards will be removed from the working register and placed in the closed or inactive files. When reactivation is manifest the case card will be again placed on the register. Visible registers have already been set up in seventeen counties, and it is expected that by July 1 registers will have been installed in every local health department. The West Virginia Tuberculosis and Health Association plans to maintain registers for counties having no active health services until local personnel can be found to assume the responsibility. A reciprocal plan for interchange of information between local and state officers has been introduced. It is important that a report be made to the bureau of tuberculosis on every active case at six month intervals. As soon as the county and state registers are operating efficiently the bureau will be equipped to do cumulative analyses for any one county or for the state as a whole.

GENERAL

Management's Responsibility in Care of Employees.—The American Association of Industrial Physicians and Surgeons, in cooperation with the radio office of the University of Chicago, announces a round table broadcast over NBC's coast to coast network, Sunday, April 14, 12:30-1 p. m., central standard time. The topic will be "What Is Management's Responsibility in the Medical Care of Its Employees?" Invited speakers include Dr. Leo Price, medical director, Union Health Center, New York; Dr. Joseph H. Chivers, medical director, Crane Company, Chicago; Dr. Franklin C. McLean, professor of pathologic physiology, University of Chicago; Dr. John J. Wittmer, assistant vice president, Consolidated Edison Company, Inc., New York, and Dr. Lloyd Shoudy, director of medical service, Bethlehem Steel Company, Bethlehem, Pa.

American Surgical Association.—The 1946 meeting of the American Surgical Association will be held at the Homestead, Hot Springs, Va., April 2-4, under the presidency of Dr. William Darrach, New York. Among the speakers will be:

Dr. Frank H. Lahey, Boston, *Pharyngoesophageal Diverticulum: Its Management and Complications.*
Drs. Hilger P. Jenkins and Rudolph W. Janda, both of Chicago, Studies on the Use of Gelatin Sponge or Foam as a Hemostatic Agent.
Dr. Francis C. Grant, Philadelphia, Results in the Surgical Treatment of Ruptured Disks.
Drs. Arthur W. Allen, Boston, and Claude E. Welch, Belmont, Mass., Subtotal Gastrectomy for Duodenal Ulcer: A Report of Personal Experiences.
Dr. Allen O. Whipple, New York, Radical Surgery in Cases of Calcification of the Pancreas.
Dr. Daniel C. Elkin Atlanta, Ga., and Major Max H. Harris, M. C., Arteriovenous Aneurysm of the Vertebral Vessels: Report of 8 Cases.
Dr. Mercier Fauteux, Westmont, Que., Surgical Treatment of Angina Pectoris: Experiences with Ligation of the Great Cardiac Vein and Pericoronary Neurectomy.

Manuscripts Invited for Norton Medical Award.—The book publishing firm of W. W. Norton and Company announces that it is again inviting manuscripts for submission to be considered for the Norton Medical Award of $3,500 offered to encourage the writing of books on medicine and the medical profession for the layman. The first such award was made to The Doctor's Job, by Dr. Carl A. L. Binger, New York, published last spring, which gave the doctor's point of view on his work. The second was given to Dr. Edward H. Hume, New York, for his book Doctors East, Doctors West, to be published May 3 (The Journal, March 16, p. 728). Closing date for submission of manuscripts this year is November 1. All particulars relating to requirements and terms may be had by addressing W. W. Norton and Company, Inc., 70 Fifth Avenue, New York 11.

Public Health Association Opens Washington Office.—The subcommittee on medical care of the American Public Health Association, through a grant from the Rockefeller Foundation, has been enabled to establish an office in Washington with a full time technical staff and, according to its news bulletin, will turn its attention immediately to a review of proposed federal and state legislation, recommending to the association the stand it should take with regard to such legislation in the light of the declared principles. The subcommittee will provide information on the medical care problems to the public health profession and will attempt to stimulate leadership in the formation and stimulation of medical care programs. Also, according to the bulletin, it hopes to formulate in detail the specifications of a suitable medical care program and to describe the steps by which such a program can be established, including its organization, financing and administration. Howard M. Kline, Ph.D., has been appointed technical secretary.

Red Cross Establishes Division of Health Services.—The American Red Cross has established an "Office for Health Services" under the direction of a vice chairman for health services. Dr. G. Foard McGinnes has been appointed vice chairman. To the office for health services have been transferred the personnel and functions of (*a*) the office of the medical director, (*b*) nursing services, (*c*) first aid, water safety and accident prevention services, (*d*) nutrition service, (*e*) disaster medical and nursing service and (*f*) medical adviser, G. S. O. The vice chairman for health services is to be the principal health officer of the organization and is to provide for and supervise all liaison with the Offices of the Surgeons General of the Army, Navy and Public Health Service and other medical and health agencies. Cooperating with other vice chairmen, the vice chairman for health services will come under special offices in the area offices. He is also to have similar relationships to the Junior Red Cross, the college units and the insular and foreign operations.

American Association of Anatomists.—The fifty-ninth session of the American Association of Anatomists will be held in Cleveland, April 4-6, with Dr. Jacob P. Schaeffer, Philadelphia, acting as president. The program will be divided between Western Reserve University School of Medicine and the Hotel Statler. Included among the speakers will be:

Joseph E. Markee, Ph.D., Durham, N. C., The Morphological Basis for Menstrual Bleeding.
William F. Windle, Ph.D., and Roland F. Becker, Ph.D., both of Chicago, An Experimental Study of Neonatal Asphyxia.
Drs. Elisha S. Gurdjian and H. R. Lissner, M.S., both of Detroit, Study of Deformations of the Skull by the "Stresscoat" Technic.
James B. Hamilton, Ph.D., Brooklyn, A Secondary Sexual Character That Develops in Man but Not in Women on Aging of an Organ Present in Both Sexes.
Dr. Richard S. Farr, Chicago, Experiments on the Fate of the Transfused Leukocyte.
Edward A. Boyden, Ph.D., Minneapolis, Analysis of Variations of the Bronchopulmonary Segments in the Left Upper Lobes of Fifty Lungs.
Dr. William B. Atkinson, New York, The Production of Ovarian Hormones During Lactation in the Mouse.

Conference on Rural Health.—The first annual National Conference on Rural Health will be held at the Palmer House, Chicago, March 30. Sponsored by the Farm Foundation and the American Farm Bureau Federation, the session will be attended by representatives from each of these groups as well as from the National Grange, the National Farmers' Union and other farm agencies. The conference will follow immediately a three day meeting in Chicago of the Midwest leaders of the farm bureau and two farm representatives from each state as well as two or more representatives from each of the forty-nine state medical societies, including the District of Columbia. The program will include:

Dr. Franklin S. Crockett, Lafayette, Ind., chairman, Committee on Rural Medical Service, American Medical Association, Purpose of Conference.
Dr. Olin West, Chicago, Secretary and General Manager, American Medical Association, Address of Welcome.

Ransom E. Aldrich, Jackson, Miss., chairman, medical care committee, American Farm Bureau Federation.

Dr. Frederick R. Mott, Washington, D. C., U. S. Public Health Service, chief medical officer, Farm Security Administration, A Public Health Program for Rural Areas.

Howard Strong, Washington, D. C., secretary, health advisory council, U. S, Chamber of Commerce, Health Program for Small Communities.

Leland B. Tate, Ph.D., Chicago, rural health services, The Farm Foundation, Health Education for American Farmers.

Hon. J. Percy Priest, Nashville, Congressman, Sixth District, Tenn.

Included among the discussers on the program will be Dr. Leonard W. Larson, Bismarck, N. D., member, Committee on Rural Medical Service, American Medical Association; Dr. Victor Johnson, Secretary, Council on Medical Education and Hospitals; American Medical Association, and Mrs. Charles W. Sewell, Chicago, administrative director of Associated Women of the American Farm Bureau Federation. Covered in the formal program will be discussion of distribution of physicians, the proposed expansion of hospital and clinical facilities in rural areas as contemplated in the Hill-Burton bill now pending in Congress, physician benefits in returning to rural practice after completing an internship and health education of the rural population.

Aero Medical Association.—The seventeenth meeting of the Aero Medical Association of the United States will be held at the Edgewater Beach Hotel, April 7-9, under the presidency of Brig. Gen. Eugen I. G. Reinartz, United States Army. Speakers will include:

Col. Major S. White, M. C., Global Aviation Medicine in the Air Transport Command.

Major George M. Hass, M. C., The Effect of Aircraft Accidents on the Future of Flying Personnel.

Dr. Andrew C. Ivy, Chicago, Future of Research in Aviation Medicine.

Major George A. Hallenbeck, M. C., Parachute Opening Shock.

Dr. Thomas C. Gentry, New York, Aero Medical Experiences in China.

William G. Clark, Ph.D., Minneapolis, and Lieut. Comdr. Ralph L. Christy Jr. (MC), Use of the Human Centrifuge in the Indoctrination of a Navy Fighter Squadron in the Use of the Antiblackout Suit.

Capt. John B. Hickam, M. C., Studies of Missile Casualties in Fliers.

Col. Arnold D. Tuttle, U. S. Army, Ret., Chicago, Passenger Comfort in Commercial Aviation.

Major Edward C. White, M. C., and Lieut. Col. Randolph L. Clark Jr., M. C., The Management of Surgical Emergencies Following Aircraft Accidents.

Wing Comdr. Wilbur R. Franks, Royal Canadian Air Force, Acceleration—Certain Aspects.

Lieut. (jg) John L. Patterson Jr. (MC) and Capt. Ashton Graybiel (MC), A Simple Test of Physical Fitness for General Use.

Capt. Grace H. Stakeman, A. N. C., Medical Care of Casualties in Long Distance Air Evacuation.

Comdr. Howard R. Bierman, MC(S), U.S.N.R., Crash Injury.

Lieut. Col. Paul M. Fitts, A. C., Psychologic Requirements in Aviation Equipment Design.

Brig. Gen. Malcolm C. Grow, M. C., The Use of Body Armor in Aviation During Wartime.

William L. Burkhardt, Ph.D., Dr. Ivy, Dr. Arthur J. Atkinson and Howard Adler. Ph.D., Chicago, A Roentgenographic Study of Bends and Chokes at Altitude.

Major Gen. David N. W. Grant, Washington, D. C., Air Evacuation Activities.

Dr. Herbert Graebner, New York, Auditory Deterioration in Airline Pilots.

Lieut. Comdr. B. G. King, H(S), U. S. N. R., Mechanisms in Anoxia.

Lieut. Col. Robert C. Anderson, M. C., The Motivations of the Flier and His Reactions to the Stress of Flying.

Lieut. M. Henson, H(W), U.S.N.R., and Lieut. E. P. Vollmer H(S), U.S.N.R., Practical Considerations in Protection Against Anoxia.

Capt Francis E. Randall, A. C., Physical Principles Involved in Pilot Comfort and Efficiency.

Lieut. D. E. Goldman, H(S), U.S.N.R., Mechanical Forces Acting on Aviation Personnel.

Dr. Robert W. Keeton, Chicago, Civilian Aviation and Medical Education.

Wing Comdr. James K. W. Ferguson, Royal Canadian Air Force, Pulmonary Ventilation and Oxygen Requirements in Aircraft.

Capt. Fred S. Grodins, M. C., Capt. A. Lein, A. C., and Lieut. H. Adler, A. C., Changes in the Acid Base Balance in the Blood During Asphyxia and Resuscitation.

Dr. Austin E. Lamberts, Ann Arbor, Mich., Emergency Aid by Air in Isolated Regions.

Dr. William R. Stovall, Washington, D. C., Aviation Medicine and Physical Standards for Airmen.

Mr. Malcolm Y. McCormick, Washington, D. C., A Statistical Consideration of Physical Examinations and Performance Records.

Charles Sheard, Ph.D., Rochester, Minn., The Influence of Certain Physical and Physiologic Factors for Aero Medical Significance on the Rod and Cone Dark Adaptation.

J. B. Bateman, Ph.D., Rochester, Minn., The Effects of Pressure Breathing on the Skin Temperature of Extremities.

CORRECTION

Annual Conference of Secretaries and Editors.—In The Journal, March 9, page 647, appears the report of the Annual Conference of Secretaries and Editors. On page 652 is a discussion credited to Mr. H. T. Sethman, executive secretary of the Colorado State Medical Society. This should have been credited to Dr. A. C. Sudan of Kremmling, Colo., president-elect of the Colorado State Medical Society.

Government Services

New Head of Coast Guard Medical Division

Rear Admiral Paul M. Stewart, formerly chief inspection officer, Office of the Surgeon General of the U. S. Public Health Service, has been appointed chief of the Coast Guard Medical Division. Dr. Stewart graduated at the University of Cincinnati College of Medicine in 1914 and has been a member of the U. S. Public Health Service since 1914.

Laboratory Aides Ill From Research

The U. S. Public Health Service has reported that in its research to determine a cure for Q fever 22 laboratory workers have been stricken, 5 are in hospitals and 1, a woman elevator operator aged 70, is near death, according to press reports March 3. Other new cases were "suspected" among the 100 employees at the laboratory at Bethesda, Md. The research has been going on since the end of the war. According to Dr. Charles Armstrong, chief of the infectious disease division of the laboratory, while the disease is apparently communicable there is no reason to believe that the outbreak will spread beyond the laboratory. Dr. Armstrong, who has recovered from the disease, thinks he is now immune.

Examinations in Public Health Service

Examinations for appointments of medical officers in the regular corps of the U. S. Public Health Service will begin April 4 at various convenient localities throughout the country. Examinations are for appointments to fill vacancies of assistant surgeon (first lieutenant) and senior assistant surgeon (captain). Regular corps appointments are permanent. They provide qualified doctors with opportunities for a career in one or more of a number of fields, including research, general hospitals, special hospitals, foreign duty and public health programs. Assignments are made according to careful consideration of the officers' demonstrated abilities and experiences. It is expected that doctors now leaving the armed services will find the openings of particular interest. Entrance pay for assistant surgeon with dependents is $3,411 a year and for senior assistant surgeon with dependents is $3,991 a year. Promotions are at regular intervals up to and including the grade of medical director, which corresponds to full colonel at $7,951 a year. Retirement pay at 64 is $4,500 a year. Full medical care, including disability retirement at three-fourths pay, is provided. All expenses of official travel are paid by the government. Thirty days' annual leave with pay is provided. Applicants for the grade of assistant surgeon must be citizens of the United States, must present a diploma of graduation from a recognized medical school, must have had or be in the process of completing the seventh year of college or professional training or experience since high school graduation (two years premedical, four years of medicine, one year internship) and must have a physical examination at the place of oral examination by medical officers of the service. Applicants for the grade of senior assistant surgeon must meet the foregoing requirements and must have had four additional years of postgraduate training or experience.

Examinations will be oral and written. The written examination will be held on May 14, 15 and 16 at places convenient to the candidate and the service. National Board grades may be used for the assistant surgeon examination. The oral examination will be held at 9 a. m. at:

Atlanta, Ga.—Malaria Control in War Areas, 605 Volunteer Bldg., April 22.
Baltimore—Marine Hospital, Wyman Park Drive and 31st St., May 9.
Boston—Marine Hospital, 77 Warren St. (Brighton), May 6.
Chicago—Marine Hospital, 4141 Clarendon Ave., April 30-May 1.
Cleveland—Marine Hospital, Fairhill Road and E. 124th St., May 3.
Denver—617 Colorado Bldg., April 8.
Detroit—Marine Hospital, Windmill Pointe, May 2.
Fort Worth, Texas—U. S. Public Health Service Hospital, April 25.
Kirkwood, Mo., near St. Louis—Marine Hospital, 525 Couch Ave., April 26-27.
Los Angeles—U. S. P. H. S. Relief Station, 406 Federal Bldg., April 9.
Minneapolis—Office of Indian Affairs, 218 Federal Office Bldg., April 29.
New Orleans—Marine Hospital, 210 State St., April 23-24.
New York—Marine Hospital, Stapleton, Staten Island, May 7-8.
Norfolk—Marine Hospital, Hampton Blvd., Larchmont, May 10.
San Francisco—Marine Hospital, 14th Ave. and Park Blvd., April 10-11.
Seattle—Marine Hospital, Judkins and 14th Ave. South, April 12-13.
Washington, D. C.—U. S. P. H. S. Dispensary, Fourth and D Streets S.W., April 4 and May 13.

Application forms may be obtained by writing to the Surgeon General, U. S. Public Health Service, Washington 25, D. C.

Deaths

Charles F. Read ⊕ Elgin, Ill.; Rush Medical College, Chicago, 1901; born in Nevada, Iowa, May 27, 1876; specialist certified by the American Board of Psychiatry and Neurology, Inc.; formerly professor of neurology and psychiatry at the Loyola University School of Medicine and assistant professor of psychiatry at the University of Illinois College of Medicine, both in Chicago; past president of the Chicago Neurological Society and the Illinois Psychiatric Society; member of the National Committee for Mental Hygiene; state alienist from 1921 to 1925; since 1930 managing officer of the Elgin State Hospital; formerly managing officer of the East Moline (Ill.) State Hospital and the Chicago State Hospital; at one time staff physician and assistant superintendent of the State Hospital, Kankakee; formerly on the staffs of the Oak Park (Ill.) Hospital and the Mercy and Garfield Park hospitals in Chicago; editor, Manual for State Hospital Attendants and Elgin State Hospital Papers; awarded the honorary degree of doctor of science from Beloit (Wis.) College at its centennial convocation; died March 11, aged 69.

Maximilian Arthur Ramirez ⊕ New York; University and Bellevue Hospital Medical College, New York, 1912; born in Cuba May 17, 1891; professor of medicine at the New York Polyclinic Medical School and Hospital; specialist certified by the American Board of Internal Medicine; past president of the Medical Society of the County of New York; fellow of the American College of Physicians and the New York Academy of Medicine; served during World War I; Chevalier of the French Legion of Honor; attending physician and director of the second medical division of the French Hospital; attending physician, New York City Hospital, Welfare Island; attending physician, Municipal Sanatorium, Otisville; consulting physician, St. Francis Hospital, Poughkeepsie, St. Agnes Hospital, White Plains, and Downtown Hospital; died March 4, aged 54.

Robert Ward Lamson ⊕ Los Angeles; Harvard Medical School, Boston, 1925; born in Amherst, Mass., July 22, 1889; professor of medicine (preventive medicine and public health) at the University of Southern California School of Medicine; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; member of the American Association for the Study of Allergy; interned at the Stanford University Hospital in San Francisco; member of the staff, Hospital of the Good Samaritan; senior outpatient department, Los Angeles County Hospital; consulting surgeon, Santa Fe Coast Lines Hospital; in charge of allergy clinic, Eye and Ear Hospital and Olive View (Calif.) Sanatorium; died in St. Vincent's Hospital December 31, aged 56, of pneumonia.

A. Bern Hirsh ⊕ New York; Jefferson Medical College of Philadelphia, 1882; born in Lancaster, Pa., March 21, 1858; an Affiliate Fellow of the American Medical Association; in 1939 awarded a gold key by the American Congress of Physical Therapy for research work; in 1905 founded the *Weekly Roster and Medical Digest*, now known as *Philadelphia Medicine*, serving as its editor until 1917; established the *New York Medical Week*, serving as its editor and managing editor of its successor, the *Journal of the Medical Society of the County of New York*; formerly chief, physical therapy and occupational therapy, U. S. Veterans Bureau; served during World War I; died in Dobbs Ferry December 21, aged 87, of senility.

Lester Emanuel Frankenthal ⊕ Chicago; Chicago Medical College, 1885; born in Chicago, April 16, 1864; for many years clinical professor of gynecology at his *alma mater*, now known as the Northwestern University Medical School; specialist certified by the American Board of Obstetrics and Gynecology, Inc.; member of the Chicago Gynecological Society and the Central Association of Obstetricians and Gynecologists; corresponding member of the Gynecological Society of Munich; fellow of the American College of Surgeons; senior attending obstetrician and gynecologist at the Michael Reese Hospital; formerly on the staff of St. Luke's Hospital, where he died December 19, aged 81, from complications following a fractured hip.

Nathan Pratt Sears ⊕ Syracuse, N. Y.; Johns Hopkins University School of Medicine, Baltimore, 1912; born in Syracuse, N. Y., in 1886; professor of gynecology at the Syracuse University College of Medicine; specialist certified by the American Board of Obstetrics and Gynecology, Inc.; member of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons and the American Gynecological Society; fellow of the American College of Surgeons; consultant, Psychopathic Hospital, Syracuse General Hospital and the Hospital of the Good Shepherd, Syracuse University; gynecologist at the Syracuse Memorial Hospital, where he died February 25, aged 60, of aortic stenosis.

Wilbert Watkins Munsell ⊕ Surgeon, Lieutenant Commander, U. S. Navy, retired, Lexington, Mass.; the Hahnemann Medical College and Hospital, Chicago, 1901; born in Naples, N. Y., April 3, 1878; member of the Medical Society of the State of New York; entered the U. S. Naval Reserve as a lieutenant (jg) on May 14, 1918; transferred to the medical corps of the regular navy on May 19, 1921; placed on the retired list on Sept. 1, 1940 with the rank of lieutenant commander and because of exigencies of the service was retained on active duty; returned to inactive duty status on Jan. 15, 1943; died in the Memorial Hospital, Easton, Md., Sept. 22, 1943, aged 65, of intestinal obstruction.

Henry Mitchell Smith ⊕ Brooklyn; Long Island College Hospital, Brooklyn, 1893; born in 1870; emeritus professor of ophthalmology at his *alma mater*, where he first served in 1908 as instructor in diseases of the eye and later as clinical professor of diseases of the eye and for many years as professor of ophthalmology and head of the department; specialist certified by the American Board of Ophthalmology; fellow of the American College of Surgeons; consulting ophthalmologist at the Long Island College Hospital; served on the staffs of the Nyack (N. Y.) Hospital, Brooklyn Eye and Ear and Coney Island hospitals; died suddenly February 23, aged 75, of cerebral hemorrhage.

William Henry Lloyd ⊕ Major, U. S. Army, retired, Mount Victoria, Md.; University and Bellevue Hospital Medical College, New York, 1900; served during the Spanish-American War, as a captain in the New Mexico National Guard and in World War I; began active duty in the medical reserve corps of the U. S. Army as a first lieutenant on April 26, 1914, in 1917 becoming a major in the medical section of the Officers Reserve Corps; entered the medical corps of the U. S. Army as a major on July 1, 1920; retired Nov. 30, 1935 at his own request after twenty-two years' service; died February 14, aged 68, of coronary thrombosis.

Robert Lonial Bailey ⊕ Bremerton, Wash.; University of Texas School of Medicine, Galveston, 1934; interned at the Providence Hospital in Seattle; served a residency at the Northern State Hospital, Sedro Woolley, and on the staff of the Eastern State Hospital at Medical Lake; chief of medicine at Roosevelt Hospital, where he died December 31, aged 41, of cerebral hemorrhage.

Thomas Chenowith Baldwin ⊕ Port Orchard, Wash.; Rush Medical College, Chicago, 1903; chief medical examiner for Kitsap County during World War I; served as county health officer; staff physician, Washington's Veterans' Home in Retsil; medical examiner for the Metropolitan Life Insurance Company, New York Life and the Equitable Life Assurance companies; died in Virginia Mason Hospital, Seattle, December 6, aged 67, of carcinoma of the bile ducts.

Amos Willis Ball ⊕ Rushville, Ill.; Missouri Medical College, St. Louis, 1886; served as president of the Schuyler County Medical Society and on the local school board; died December 8, aged 84.

William Wesley Ballaine, Bellingham, Wash.; Kentucky University Medical Department, Louisville, 1902; member of the American Medical Association; past president of the Whatcom County Medical Society; in 1928 retired as health officer of Bellingham after twenty years of service; member and medical examiner for the local draft board during World War I; captain, medical reserve corps, U. S. Army, not on active duty; died December 1, aged 67.

William Martin Bigger, Hammond, Ind.; Medical Department of the Western University of Pennsylvania, Pittsburgh, 1897; member of the American Medical Association; served during World War I; died in St. Margaret Hospital December 30, aged 74, of uremia and chronic general vascular arteriosclerosis.

Alfred S. Black, Charleston, W. Va.; Medical College of Virginia, Richmond, 1902; died in a local hospital December 8, aged 83, of pneumonia.

John James Board, Rustburg, Va.; Jefferson Medical College of Philadelphia, 1880; member of the American Medical Association; died December 30, aged 86, of heart disease.

William Riley Bonds, Winfield, Ala.; Medical College of Alabama, Mobile, 1892; died December 25, aged 82, of carcinoma.

Ira Edgar Bowman, Odon, Ind.; Indiana University School of Medicine, Indianapolis, 1910; member of the American Medical Association; died in the Daviess County Hospital, Washington, December 30, aged 64, of carcinoma of the lung.

Ctimir Silas Brazda, Los Angeles; University of Illinois College of Medicine, Chicago, 1942; interned at the Los Angeles County Hospital, where he served a residency; also a D.D.S.; attending oral surgeon at the Los Angeles County General Hospital, the Queen of Angels Hospital and the Alhambra (Calif.) Hospital; died December 8, aged 46.

Bert Barrett Bruce, Alma, Ark.; Kansas City (Mo.) College of Medicine and Surgery, 1919; member of the American Medical Association; served as president and secretary of the Crawford County Medical Society; formerly county coroner; died December 13, aged 68, of generalized arteriosclerosis and acute coronary occlusion.

Annie Sophia Bullock ⊕ Alhambra, Calif.; Woman's Medical College of Pennsylvania, Philadelphia, 1912; on the staffs of the Alhambra Hospital, Alhambra, and the Garfield Hospital, Monterey Park; died December 6, aged 72, of cerebral hemorrhage.

Oscar Newton Clark, Greeley, Kan.; Eclectic Medical University, Kansas City, Mo.; 1915; Kansas City (Mo.) College of Medicine and Surgery, 1920; member of the American Medical Association; died December 7, aged 59, of coronary thrombosis.

Adolphus Jackson Crider ⊕ Dixon, Mo.; St. Louis University School of Medicine, 1910; died December 2, aged 60, of coronary occlusion.

Garland Franklin Cummins, Nashville, Tenn.; University of Nashville Medical Department and Vanderbilt University School of Medicine, Nashville, 1895; died in the Protestant Hospital December 15, aged 81.

John Francis Curtin ⊕ Minneapolis; Harvard Medical School, Boston, 1915; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; served during World War I; on the staffs of the Asbury, Northwestern and St. Mary's hospitals; president of the medical staff of the Abbott Hospital; died December 25, aged 56, of carcinoma of the liver and sigmoid.

Charles Henry Cutler ⊕ Peterborough, N. H.; University of Vermont College of Medicine, Burlington, 1892; served as health officer and school physician; on the staff of the Peterborough Hospital; died December 22, aged 78, of arteriosclerosis.

John Edgar Davis ⊕ Columbus, Miss.; Medical Department of Tulane University of Louisiana, New Orleans, 1889; served during World War I; died December 1, aged 78, of cardiorenal disease.

Joseph Vance Davis, Waynesville, N. C.; University of Pennsylvania School of Medicine, Philadelphia, 1945; found dead November 8, aged 24, near the administration building of the Peter Bent Brigham Hospital, Boston, where he was serving an internship.

Mary E. Snyder Davis, Colwyn, Pa.; Woman's Medical College of Pennsylvania, Philadelphia, 1892; died December 1, aged 80, of hypertensive cardiovascular disease.

J. Mercer Dickerson, Peoria, Ill.; Barnes Medical College, St. Louis, 1908; found dead in bed December 2, aged 69.

George McCready Dickson ⊕ Adamsburg, Pa.; Medical Department of the Western University of Pennsylvania, Pittsburgh, 1902; served during World War I; on the staff of the Westmoreland County Hospital, Greensburg, where he died December 13, aged 70, of carcinoma of the left lung and rheumatic heart disease.

Ernestine Doychert, Tucson, Ariz.; Medical Department of the University of California, San Francisco, 1900; died in St. Mary's Hospital December 1, aged 66, of coronary occlusion and chronic arthritis.

Daniel John Fennelly ⊕ Boston; Tufts College Medical School, Boston, 1911; served during World War I; neuropsychiatrist for the Veterans Administration in the Fall River area; on the staffs of the St. Luke's Hospital in New Bedford, Mass., and the Union and St. Anne's hospitals in Fall River; died December 20, aged 59, of coronary thrombosis.

Henry Andrew Fisher ⊕ Brooklyn; Long Island College Hospital, Brooklyn, 1909; member of the American Urological Association; fellow of the American College of Surgeons; specialist certified by the American Board of Urology, Inc.; served during World War I; colonel, medical reserve corps, U. S Army, not on active duty; formerly attending urologist, Brooklyn Hospital and Norwegian Lutheran Deaconesses' Home and Hospital; died December 4, aged 59.

Julius Frankel, New York; Cornell University Medical College, New York, 1900; formerly on the staffs of the Beth Israel, Manhattan General and St. Mark's hospitals; died in Miami, Fla., December 7, aged 70, of heart disease.

Vance A. Funk ⊕ Vincennes, Ind.; University of Nashville Medical Department, 1909; fellow of the American College of Surgeons; on the staff of the Good Samaritan Hospital; died December 31, aged 63, of coronary occlusion and arteriosclerosis.

Raymond V. Glann, Baltimore; Maryland Medical College, Baltimore, 1904; member of the American Medical Association; died December 4, aged 67, of coronary disease.

Stewart Hamilton, Detroit; Northwestern University Medical School, Chicago, 1905; also a graduate in pharmacy; member of the Michigan Hospital Association and the American Hospital Association; at one time instructor in pathology at the Detroit College of Medicine; medical director of the Harper Hospital; formerly assistant surgeon to the Copper Range Mining Company in Upper Peninsula; served during World War I; died December 18, aged 65, of cerebral hemorrhage.

John Thomas Hanna, Burlington, Iowa; State University of Iowa College of Medicine, Iowa City, 1915; served as acting assistant surgeon in the U. S. Public Health Service; major, medical reserve corps, U. S. Army, not on active duty; died in Milwaukee December 18, aged 55, of lobar pneumonia.

Edmund Lee Harrison, Kansas City, Mo.; University Medical College of Kansas City, 1892; member of the American Medical Association; formerly associated with the U. S. Veterans Bureau; died December 23, aged 82, of chronic myocarditis and arteriosclerosis.

Isaiah William Haughey ⊕ Fort Collins, Colo.; State University of Iowa College of Medicine, Iowa City, 1889; served during World War I; on the staff of the Larimer County Hospital; died December 5, aged 77, of cerebral hemorrhage.

James Worrall Henry, Cheyenne, Okla.; Columbia University College of Physicians and Surgeons, New York, 1912; member of the American Medical Association; died in Anadarko, December 26, aged 57, of congestive heart failure.

Gerhard William Heuser ⊕ Brooklyn; Cornell University Medical College, New York, 1904; on the staff of the Swedish Hospital, where he died December 29, aged 65, of coronary occlusion, bronchopneumonia and arteriosclerotic heart disease.

Carl R. Hiller ⊕ Cincinnati; Medical College of Ohio, Cincinnati, 1899; professor emeritus of clinical surgery, University of Cincinnati College of Medicine; member of the founders group of the American Board of Surgery; fellow of the American College of Surgeons; member of the board of trustees and past president of the College of Music; on the staffs of the Good Samaritan Hospital, Cincinnati General Hospital and the Jewish Hospital, where he died December 3, aged 68, of heart disease.

Benjamin Franklin Horner, Otsego, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1887; formerly member of the board of directors of the bank; on the staff of the Borgess Hospital in Kalamazoo, where he died December 16, aged 82, of complications due to a fractured hip received in a fall on the ice.

Siegfried Ickelheimer, Woodside, N. Y.; Ludwig-Maximilians-Universität Medizinische Fakultät, Munich, Bavaria, Germany, 1919; served in the German army during World War I; died December 16, aged 58.

John Dee Jackson ⊕ Kerrville, Texas; Washington University School of Medicine, St. Louis, 1914; member of the American College of Chest Physicians; on the staff of the Kerrville General Hospital; died suddenly December 31, aged 55, of heart disease.

Josephine Agnes Jackson, Long Beach, Calif.: Northwestern University Woman's Medical School, Chicago, 1896; Rush Medical College, Chicago, 1903; member of the American Medical Association; author of "Outwitting Our Nerves"; at one time on the staff of the Cook County Hospital in Chicago; died in Palo Alto December 31, aged 80, of heart disease and arteriosclerosis.

Archie Nelson Johnson, Kansas City, Mo.; University Medical College of Kansas City, 1903; member of the American Medical Association; member of the staff of St. Joseph Hospital; died in the Veterans Administration Facility, Wadsworth, Kan., December 6, aged 78.

Albert Bates Jones, Camano, Wash.; Maryland Medical College, Baltimore, 1904; died November 3, aged 74.

Boris Kaplan ⊕ New Bedford, Mass.; University of Saratov Faculty of Medicine, Russia, 1918; member of the National Gastroenterological Association; a major and medical officer in the Russian Imperial Army during World War I; on the staff of St. Luke's Hospital, where he died December 25, aged 56, of coronary thrombosis.

Brian Joseph Kelly ⊕ Frankfort, N. Y.; University and Bellevue Hospital Medical College, New York, 1915; mayor of Frankfort; past president of the board of education; chairman of the Herkimer County Democratic Committee; on the staffs of the Herkimer (N. Y.) Hospital, Little Falls (N. Y.) Hospital, Ilion (N. Y.) Hospital and St. Elizabeth Hospital in Utica; division surgeon New York Central Railroad; died December 17, aged 54, of coronary thrombosis.

Charles Anselm Kersey, Muncie, Ind.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1872; died December 23, aged 100, of bronchopneumonia.

Commodore Marvin Kimble, Paden City, W. Va.; Maryland Medical College, Baltimore, 1912; served as mayor of Paden City; on the staff of the Wetzel County Hospital, New Martinsville; died in the Johns Hopkins Hospital, Baltimore, December 14, aged 63, of carcinoma of the bladder.

Martin Smith Kirwan, Louisville, Ky.; Kentucky School of Medicine, Louisville, 1906; died in the SS Mary and Elizabeth Hospital December 23, aged 69, of hypertensive cardiovascular renal disease.

Joseph James Kotershall ⊕ Cleveland; University of Wooster Medical Department, Cleveland, 1903; for many years on the staff of St. John's Hospital; died December 10, aged 64, of arteriosclerotic heart disease.

Lieut. Alexander Henry Davis
(MC), U.S.N.R., 1906-1945

Capt. Lloyd B. James
M. C., A. U. S., 1906-1945

Lieut. Comdr. Alfred L. Lyons
(MC), U.S.N.R., 1899-1945

Albert Lenz ⊕ Schenectady, N. Y.; Albany (N. Y.) Medical College, 1912; member of the Radiological Society of North America, Inc.; consultant roentgenologist at the Mary McClellan Hospital in Cambridge; on the staff of the City Hospital; consulting surgeon, Ellis Hospital; died February 20, aged 57, of uremia and chronic nephrosclerosis.

George Mannheimer ⊕ New York; Kaiser-Wilhelms Universität Medizinische-Fakultät, Strassburg, Germany 1889; fellow of the American College of Physicians; consulting physician, New York Infirmary for Women and Children; died in the Mount Sinai Hospital December 10, aged 78, of cerebral hemorrhage.

James Walsh McClaran ⊕ Jackson, Tenn.; Vanderbilt University School of Medicine, Nashville, 1911; member of the Southeastern Surgical Congress; fellow of the American College of Surgeons; decorated by the French government for service with the French army during World War I; transferred to the American army on the entry of the United States into the war; division surgeon, Gulf, Mobile and Ohio Railroad; on the staff of the Memorial Hospital, where he died December 27, aged 57, of cerebral hemorrhage.

Edwin Taylor Morris ⊕ San Benito, Texas; University of Texas School of Medicine, Galveston, 1912; local physician and surgeon for the Missouri Pacific Railroad; died in Harlingen November 25, aged 58, of congestive heart disease.

James C. Mudd, Springfield, Ky.; Kentucky School of Medicine, Louisville, 1897; member of the American Medical Association; died December 1, aged 75, of heart disease.

Rudolf Patek, New York; Medizinische Fakultät der Universität Wien, Vienna, Austria, 1908; served a residency at the Sea View Hospital; died in the Westside Hospital November 17, aged 63, of pulmonary embolism following a prostatectomy.

Maurice Schneck ⊕ Forest Hills, N. Y.; Long Island College Hospital, Brooklyn, 1911; died February 25, aged 60, of coronary thrombosis.

KILLED IN ACTION

Alexander Henry Davis ⊕ Chicago; the School of Medicine of the Division of Biological Sciences, University of Chicago, 1932; interned at the University of Chicago Clinics; at one time affiliated with the Johns Hopkins Hospital in Baltimore; began active duty as a lieutenant in the medical corps of the U. S. Naval Reserve on Dec. 10, 1942; assigned to the U. S. Naval Hospital in San Diego; killed in the Asiatic area April 28, 1945, aged 39, when his ship, the U. S. S. *Pinckney*, was hit by a suicide bomber

Lloyd Bertram James ⊕ Fresno, Calif.; College of Medical Evangelists, Loma Linda-Los Angeles, 1932; interned at the Orange County Hospital in Orange; diplomate of the National Board of Medical Examiners; began active duty as a first lieutenant in the medical corps, Army of the United States, in September 1942; promoted to captain; flight surgeon in the Air Corps; killed in action in Tinian July 3, 1945 aged 39.

Alfred Labori Lyons ⊕ Flushing, N. Y.; Vanderbilt University School of Medicine, Nashville, Tenn., 1928; interned at the Long Island College Hospital in Brooklyn; formerly resident physician at the Clifton Springs Sanitarium and Clinic in Clifton Springs; on the staffs of the Queens General, Mary Immaculate and Triboro hospitals, all in Jamaica; served with the Canadian army during World War I; began active duty as a lieutenant commander in the medical corps of the U. S. Naval Reserve on Sept. 27, 1943; killed in action in the Pacific area April 28, 1945, aged 45, when a Japanese suicide plane crashed into an auxiliary hospital transport off Okinawa

The Minister Who Won't Negotiate

It has been shown in previous letters that the scheme for a national health service is but the climax of the socialistic trend of British politics for many years. So strong is this trend that the scheme was introduced by a government in which the conservative party was predominant. The great majority of the medical profession were opposed to the scheme, but they had a conservative minister of health, with whom they could negotiate. The position changed much for the worse when a socialist government took the place of the coalition government. The conservative minister was immediately denounced for "surrendering to the doctors," though he had only negotiated with them, and his place was taken by a socialist, Mr. Bevan, who listens to the representatives of the medical profession but will not negotiate. He has put before them his proposals, which they are precluded from circulating to the profession because they are confidential. He has listened to the comments and criticisms of the negotiating committee of the profession but withheld his response until he has brought in the bill in the House of Commons. At the moment the position is one of complete calm—the calm before the storm. The *British Medical Journal* points out that, while Mr. Bevan is acting within his rights as a minister in not discussing his proposals, he would not be acting outside them if he freely exchanged views across the table with those chosen to represent the profession. It quotes with approval from the *Observer* "In its doctrinaire passion for nationalizing as much as possible as fast as possible" the cabinet "is minding everybody's business except its own."

Student Health Care Unsatisfactory

The Royal College of Physicians has published a report from its social and preventive medicine committee on student health services. Although the problem of sickness among university students is serious, many university authorities are indifferent to corrective measures. Only perfunctory attention, from the point of view of health, is paid in some instances to matters of diet and lodgings. The report recommends that the universities accept greater responsibility for the health of students. Arrangements should be made for medical examination on entry and for periodic examinations while at the university. Medical nursing care should be available to students who are ill. Inspection of lodgings should be undertaken by special officers of the university. It is recommended that the diet of students be improved, including the provision of canteens. It is further suggested that a special medical officer might do for universities and colleges what an industrial medical officer does in an enlightened industrial concern. What appears to be the first appointment of this kind has been made by the University of Aberdeen. It has appointed a full time physician at a salary of $4,280 a year to be in charge of the student health service.

The Danger of Vaginal Insufflation During Pregnancy

The danger of vaginal insufflation during pregnancy is shown by a case reported by Dr. C. H. Walsh to the North of England Obstetric and Gynecologic Society. A primigravida aged 17 was treated with picratol insufflations for leukorrhea at about the thirtieth week of pregnancy. The first insufflation did not produce discomfort. A week later insufflation was performed by a nurse with the patient lying in the left lateral position. Six or seven compressions of the insufflator bulb were made. The patient rapidly became cyanotic and dyspneic, became unconscious and died within five minutes. Necropsy revealed a fetus of thirty to thirty-one weeks' gestation. The placenta was attached to the posterior upper segment of the uterus. There was a small detachment at the lower border, with stripping of the membranes down to the cervix. A trace of picratol powder was found in a maternal sinus. The inferior vena cava was filled with air; the right auricle of the heart contained frothy blood. The cause of death was obstruction of a pulmonary artery and right heart failure due to air embolism.

The insufflator used delivered about 50 cc. of air and powder. If the rubber cone made an airtight connection between the introitus, six or seven compressions would introduce 350 cc. of air and powder at a pressure of at least 150 mm. Under these conditions even a small venule might absorb air, causing air embolism. Vaginal insufflation is contraindicated in pregnancy or in cases of bleeding from the uterus. Tubal insufflation should be discarded in favor of the iodized oil technic.

Tuberculosis During the Wars of 1914 and 1939

L. Moine, statistician, has published a comparative study on tuberculosis mortality in the last two wars. During the war of 1914-1918 an increase of the tuberculosis death rate was noted. The death rate rose from 215 per hundred thousand inhabitants in 1910 to 278 in 1918, an increase of 29.3 per cent. During the war of 1939-1945 and the occupation it attained 159 in 1941, the highest rate, as against 120 in 1936, which represents an increase of 32.5 per cent. The Bulletin of General Statistics of France estimates the total number of deaths from tuberculosis as 315,000 for the period from September 1939 to May 1945. Children up to 2 years of age were severely stricken. An increase of 21 per cent for adolescents from 15 to 19 and of 88.5 per cent for men from 25 to 29 has been observed. The author concludes that this increase among men is due to their greater reaction to the restrictions and the hardships of life during the war and the occupation. The difficulty of placing patients in institutions has caused an increase of contact infection in families, especially among the poor.

Activity of the Epidemiologic Service

An epidemiologic service was organized in 1944 in the Departmental Public Office of Social Hygiene. In every "département" (district) the departmental inspector represents the health authority. The service consists of a secretary and of "assistantes sociales" (district nurses). In the department of the Seine from early in 1944 to October 1945, 7,189 infected women and 681 refractory patients were reported; 35 per cent of the former and 40 per cent of the latter were found. In accordance with the sanitary convention agreed to by forty-two countries, including France, in 1939, circulars have recently been issued by the prefects closing licensed brothels.

Antivenereal Measures in the Seine District

The Ministry of Public Health has published a circular which emphasizes previous orders making it obligatory for doctors to make a plain declaration, without a name, or a nominative declaration in the case of refractory patients, to the district (department) sanitary authority for every new case of venereal disease. The doctor must submit to patients the legal notice regarding the refusal to submit to treatment. He must also communicate to the departmental health service all information from the patient concerning the probable origin of the disease.

Miscellaneous

The Society of Medical Electroradiology of France, the Society of Electrotherapy and Radiology and the French Society of Physics commemorated, at an official meeting, the fiftieth anniversary of the discovery of the x-rays.

Prof. Henri Vincent, well known through his work on typhoid vaccination and gangrene, celebrated his fiftieth anniversary as a professor at the Val-de-Grace military hospital. He is a member of the Academy of Medicine and is general medical inspector of the French army. He is 83 years old and still pursues his scientific activity.

Dr. Hartmann, ophthalmologist of the Paris Hospitals, late associate professor of ophthalmology at Columbia University, delivered a lecture on "Medicine in the United States" and on "The Life of American Doctors."

Prof. Gaston Milian has died at the age of 74. He was well known in French dermatosyphilology and was among the first who introduced arsphenamine in France. His works on reactivation of the Bordet-Wassermann test, on the theory of biotropism, to which he has given his name, and his numerous studies on dermatology are widely known. He was a member of the Academy of Medicine and president of the League Against Venereal Disease.

PUERTO RICO

(From Our Regular Correspondent)

Feb. 15, 1946.

Pending Legislation

The following bills have been introduced in the House of Representatives and the Senate, now in regular annual session:

S. B. No. 114, to appropriate the sum of $518,000 to the Department of the Interior for the construction and equipment of new municipal hospital facilities and health centers, on recommendation of the commissioner of health, and to enlarge and reconstruct existing facilities. This appropriation shall be available July 1, 1946.

S. B. No. 100, to appropriate the sum of $900,000 to the University of Puerto Rico for scholarships to medical students during the fiscal years 1946-1947 to 1951-1952 inclusive.

H. B. No. 41, to appropriate the sum of $2,100,000 for the construction of hospitals and health units in Puerto Rico, to accept the benefits of federal grants-in-aid for the construction and equipment of hospital facilities and to determine the disposition of these funds.

The following bills are opposed by the Puerto Rico Medical Association and other professional groups in San Juan:

S. B. No. 9, to amend sections 2, 3, 4 and 6 of Act No. 26 of April 10, 1942, amended by Act No. 13, Nov. 23, 1942, to authorize the Board of Medical Examiners of Puerto Rico to permit the practice of medicine by issuing temporary licenses without previous examination, to establish rules and regulations by the board of medical examiners for the admission of graduate physicians from recognized medical schools to practice medicine in Puerto Rico provided that such licenses shall be valid only until June 30, 1950 and will be subject to revocation and to the provisions of any act that affects the practice of medicine in Puerto Rico. (This law is not applicable to candidates who failed in their examinations before the Medical Board of Puerto Rico or those who had not passed the required examination before the enforcement of this act.)

S. B. No. 8 amends sections 2, 3, 4 and 6 of Act No. 26 of 1942, providing that any graduate physician from a duly recognized university, at the discretion of the Board of Medical Examiners of Puerto Rico, may ask the board to issue him a license to practice his profession in any municipality of Puerto Rico or division of the insular government during the period of emergency determined by this act and under the terms and conditions expressed by this act. The purpose of this legislation is to permit the practice of medicine in this island by foreign physicians, who are authorized by this law to request such a provisional license from the board if certain requisites are filled by the candidate. Such physicians can practice their profession privately if they sign a contract to serve with any municipality in Puerto Rico under prescribed rules and regulations of the health commissioner. All candidates, however, must show evidence that they have finished a period of hospital training in their countries of origin for a period of at least one year after graduation from a recognized university or medical college. Not more than 100 foreign physicians would be admitted in Puerto Rico under this system of special licenses during the period of emergency specified by this act.

Quinidine Substitute

An interesting article was recently published in the *Ciencia e Investigación* by Drs. Venancio Deulofeu, Rafael Labriola, Oscar Orias and E. Moisset de Espanés of Buenos Aires and Alberto C. Taquini of Córdoba. They report experiments with the alkaloid alpha-fagarine, which has effects on the heart similar to those of quinidine. The credit of having isolated several alkaloids from a nut tree of the Fagaracea family belongs to Stuckert, who obtained the alpha, beta and gamma fagarines. Trees of this genus grow in large numbers in the northern and central areas of Argentina. The Argentine authors found that the formula of alpha-fagarine is $C_{19}H_{23}NO_4$ and they obtained accurate knowledge of the chemical structure of the substance. Stuckert and Sartori, while carrying on studies on the pharmacologic effects of the substance in batrachians and rabbits, found that it depresses the heart. The results of the experiments by Moisset de Espanés and Moyana Navarro on dogs indicated that alpha-fagarine causes depression of the heart. Chronaxia of the myocardial fibers is prolonged. The threshold of tachysystole and of auricular and ventricular fibrillation (as determined by the faradic current) is increased. The effects of alpha-fagarine on the last mentioned changes are greater than those of quinidine. Alpha-fagarine rapidly controls auricular fibrillation, spontaneously developed during experimental exposure of the animal's heart, and diminishes the danger of primary ventricular fibrillation following experimental coronary occlusion in dogs, whereas quinidine lacks this effect. Rabbits and dogs tolerated doses of 5 mg. of alpha-fagarine for each kilogram of body weight by the intravenous route. The dose was administered intravenously three times a day for forty-five consecutive days. The animals did not show any toxic reactions.

Taquini administered alpha-fagarine to 6 patients with auricular fibrillation. The patients had been observed for several months before administration of the alpha-fagarine. Four patients in the group had coronary heart disease and 2 had rheumatic heart disease (mitral stenosis). Quinidine in the ordinary doses had failed in 5 cases. Alpha-fagarine was administered intramuscularly in only one dose, which varied from 0.06 to 0.10 Gm., after failure of quinidine. Sinus rhythm was reestablished within thirty minutes after administration of the drug in all cases. Because of these results the authors believe that alpha-fagarine is an important drug in the therapy of heart diseases and in certain disorders of cardiac rhythm.

Sanitation in Chile

Dr. Nacianceno Romero y O., head of the National Department of Public Health, recently published a report on the functions, aims and work carried on by the department in the last few years. They include (1) education of technicians for public sanitation, (2) work on sanitation in Chile, (3) campaigns against infectious diseases, (4) organization of units of sanitation and health centers and (5) establishment of the proper postwar sanitary measures in relations with other countries of the world. In dealing with infectious diseases it was found that the outbreak of smallpox which occurred in the northern region of Chile was imported by a foreign family who entered the country with the disease. During the epidemic 35 cases of the disease with 7 deaths were reported. In the city of Santiago 500,000 persons reported for vaccination. Certain experiments carried out in Chile resulted in the development of a combined vaccine for diphtheria and whooping cough. The vaccine is still in the experimental stage. The number of cases of typhoid is about 5,000 a year, with a death rate of 10 per cent. Tuberculosis is an acute problem in Chile. Reporting the cases is not obligatory. The disease is second as a cause of death. The number of beds available for tuberculous patients in the acute stage of infection is far below that which is necessary. The disease is epidemic throughout the country. The most necessary measure is the isolation of patients who are infectious. The patients are a menace for the health of others at home, in the streets and at work. Typhus exists but does not justify alarm. Meningococcic meningitis and scarlet fever are epidemic in the country. However, the proper statistical significance is not given to these diseases. Seven hundred cases of anthrax were reported in 1943. The disease can be prevented by proper care of workers. The laws of Chile are not satisfactory.

A law was passed in March 1943 by which the chief of the National General Department of Public Health was authorized by the government to organize an energetic crusade against venereal disease, which constitutes one of the most acute problems in Chile. Patients with early syphilis have therapy with "massive" doses of arsenicals. The treatment is administered in antisyphilitic centers. Penicillin is to be administered in certain cases. A committee for supervision of industrial hygiene and protection of workers was established in 1943. Attention has been given to possible or actual poisoning of miners working in manganese mines as well as to silicosis. General and infant mortality has diminished. The death rate of infants from birth to 1 year of age was 231 for 5,000 births of living infants in 1934 and 155 for the same number of births in 1943. The general death rate diminished from 26 deaths per thousand persons in 1934 to 19 in 1943.

Brief News Notes

Dr. Nerio Rojas, professor of legal medicine, has been appointed dean of the Faculty of Medicine of the University of Buenos Aires.

The following doctors were appointed to the Academia Nacional de Medicina: Drs. Gregorio Aráoz Alfaro and Carlos Bonorino Udaondo, president and vice president, respectively; Drs. Florencio Etcheverry Boneo and Mario J. del Carril, honorary and actual secretaries, respectively; Dr. Juan M. Obarrio, treasurer; Dr. Pedro A. Maissa, regular academic member; Drs. Fortunato Quesada and Francisco Graña (Peru) were appointed honorary Latin-American members; Dr. Carlos Enrique Paz Soldán (Peru), Latin-American corresponding member, and Dr. E. Meulengracht (Denmark), foreign corresponding member.

New branches of the hemotherapeutic center of the state are to be organized in the military hospitals of Paraná, Córdoba, Tucumán, Mendoza, Salta and Campo de Mayo by resolution of the authorities at the National Ministry of War.

Dr. Benardo A. Houssay, professor of physiology of the Faculty of Medicine of the University of Buenos Aires, was recently appointed foreign member of the Royal Academy of Sciences of Sweden.

Dr. Mariano R. Castex, regular professor of clinical medicine of the Faculty of Medicine of the University of Buenos Aires, was recently appointed doctor *honoris causa* of the university at the request of the Faculty of Medicine of Paris.

Crusade Against Tuberculosis

Dr. Livio R. Zunino is the head of the Manuel de Abreu Center for photographic and roentgen census of tuberculosis. In the five years from 1939 to 1944 examinations were carried out on 249,286 persons. The tuberculosis rate was found to be 6.68 per cent in persons who lived with patients with tuberculosis and 2.43 per cent in the group not living with tuberculous patients. The number of patients with tuberculosis discovered by the examination was 12,612 out of 249,286 persons examined. The disease was in an early stage in the majority of instances. Permanent recovery of 90 per cent of the patients was obtained with the proper therapy. Patients who are sent by their physicians to the center for x-ray examination pay 2 Argentine pesos ($0.48) for the roentgenograms, whereas those sent by dispensaries or from hospitals pay 1 Argentine peso ($0.24).

BRAZIL

(From Our Regular Correspondent)

São Paulo, Feb. 23, 1946.

Chemotherapy of Tuberculosis and Leprosy

Dr. E. Biocca read a paper before the Society of Biology of São Paulo describing his studies on the tuberculostatic value in vitro of the trichloroacetylic radical, of numerous azo compounds, of two organic cupric derivatives of sulfanilamide, of derivatives of nitroaminodiphenylsulfone and diaminodiphenylsulfone. The compounds with organic sulfur were prepared by Professor Quintino Mingoja and Dr. Berti in the Laboratório Paulista de Biologia; the others were prepared by Professor Senise in the Laboratório of Quimica of the Faculdade de Filosofia of the University of São Paulo. It has been possible for Dr. Biocca to confirm the high tuberculostatic value in vitro of the trichloroacetylic radical. This property could be shown only when the trichloroacetylic radical was bound to a benzene ring in an aminic function. The trichloroacetylic radical bound in an aminic function, without the benzene ring (trichloroacetamide) as well as a benzene ring bound to a simple acetylic group (acetanilide) did not present any evident tuberculostatic value.

Among the azo-derivatives the most evident bacteriostatic antituberculosis activity in vitro was shown by an x-benzene-B-trichloroacetylnaphthylamine.

A cupric organic derivative was strongly tuberculostatic, but at the same time highly toxic for animals. The following sulfonamides, as has been observed by several authors, were strongly tuberculostatic in vitro: sulfathiazole, sulfapyridine, sulfadiazine, sulfamerazine and N'acetylsulfanilamide.

Among derivatives of 4-nitro-4'aminodiphenylsulfone, Schiff's bases, acetylderivatives and sulfones with halogenated radicals were more effective than the formylderivative 117 M and the trichloroacetylic derivative.

Of the derivatives of 4-4' diaminodiphenylsulfone the 4-4' ditrichloroacetyldiaminodiphenylsulfone Diclorane and the 4-4' diformyldiaminodiphenylsulfone Formilone are compounds of the highest interest in the chemotherapy of alcohol-acid fast microbes.

Marriages

William Thomas Daniel, Franklin, Tenn., to Capt. Ruth Stratton, Army Nurse Corps, in Beaver Falls, Pa., February 1.

Harold Preston Burbage to Miss Zylphya Elizabeth Haywood, both of Charleston, S. C., in Columbia, December 27.

George Allyn Chapman, Shenandoah Caverns, Va., to Lieut. Gladys Fulk, Army Nurse Corps, in Richmond recently.

David Sanford Citron, Charlotte, N. C., to Miss Doris Berman of Waterbury, Conn., in St. Louis, February 14.

B. S. Henry, Darling, Miss., to Miss Emily Mary Theresa Johnston of Oxford, England, Sept. 30, 1944.

John David Taylor, Winston-Salem, N. C., to Miss Alma Louise Moore at St. Pauls, February 8.

Franklin Bernard Ott, Newark, N. J., to Miss Claire Moriarty of Maplewood, February 16.

Roy W. Johnson, Los Angeles, to Miss Merle Barfield at Riverside, Calif., December 29.

Ely Elliott Lazarus to Miss Joy Sue Koslow, both of New York, February 1.

Rotan Lee, Bushkill, Pa., to Miss Bessie O. Hart of Steelton, January 5.

Bureau of Investigation

MISBRANDED PRODUCTS

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the Federal Security Agency

[EDITORIAL NOTE.—These Notices of Judgment are issued under the Food, Drug and Cosmetic Act, and in cases in which they refer to drugs and devices they are designated D.D.N.J. and foods, F.N.J. The abstracts that follow are given in the briefest possible form: (1) the name of the product; (2) the name of the manufacturer, shipper or consigner; (3) the date of shipment; (4) the composition; (5) the reason for the charge of misbranding, and (6) the date of issuance of the Notice of Judgment.]

Bio-Mineral.—Bio-Mineral Products Company, Detroit Shipped Dec. 21 and 22, 1942, and Jan. 2, 1943. Composition: essentially a watery solution of ferric sulfate (about 3.4 grains per teaspoonful), smaller amounts of the sulfates of aluminum, calcium and magnesium, and a phosphate. Misbranded for these reasons, among others. that label falsely represented product effective for rheumatism, constipation, weak kidneys, colonic disorders, hemorrhoids and appendicitis; that despite label claims, the mixture, when taken as directed, would not supply any mineral except iron that would substantially supplement mineral deficiency, and because label statement of composition failed to mention that, of the various ingredients declared, none except ferric sulfate was of any material significance when product was taken as directed —[*D. D. N. J., F. D. C. 989, November 1944*] Later actions brought against this concern were *D. D. N. J. 1180 and 1245, both issued in June 1945.*

Domino Brand Antiseptic Rubbing Compound.—Halitosine Company, St. Louis. Shipped between Sept. 19 and Oct. 9, 1941. Composition: essentially water, isopropyl alcohol approximately 9 per cent by volume, methyl salicylate, boric acid and menthol. Misbranded because quantity was less than label stated; because of false label claim, "Antiseptic," which the product was not, and because label falsely represented that product was rubbing alcohol or its equivalent.—[*D. D. N. J., F. D. C. 935; October 1944*]

Domino Brand Superior Rubbing Compound.—Halitosine Company, St. Louis. Shipped Aug. 29 and Oct. 8, 1942 Composition: essentially water and 23 per cent of isopropyl alcohol, with small amounts of boric acid, thymol, menthol and methyl salicylate. Misbranded because name and label directions for massaging and sponging falsely represented product to be extensively marketed as a rubbing alcohol compound and to contain approximately 70 per cent of alcohol or its equivalent, whereas it contained only 23 per cent of isopropyl alcohol —[*D. D. N. J., F. D. C. 983, November 1944.*]

DPS Formula 50.—Dartell Laboratories, Los Angeles Shipped June 19 and July 9, 1942 Adulterated and misbranded because of false label claim: "Each Tablet Contains Not Less Than . . . Vitamin B_2 348 Gammas."—[*D. D. N. J., F. D. C. 968; November 1944.*] Also adulterated and misbranded under the provisions of the law applicable to foods, as reported in *F. N J. 5776*

Elixir Quinux.—S. F. Durst & Company, Philadelphia. Shipped March 20, 1942. Adulterated and misbranded because falsely represented on label to contain 2 grains of quinine sulfate per fluid ounce, whereas it contained not more than 0.42 grain of this substance per fluid ounce.—[*D D. N. J., F. D. C. 962, November 1944.*]

Formula 8-12 Vitamins-Minerals.—*Universal Products Company*, Cleveland. Shipped Jan. 10 to 14, 1943. Composition claimed on label soy bean meal, wheat embryo, gum karaya, brewer's yeast, kaolin, kelp, activated ergosterol, natural vitamin A ester, thiamin hydrochloride, riboflavin, dicalcium phosphate, iron bihydrogen (sic!), potassium iodide and oil of orange Misbranded because falsely represented that product was of significant nutritional value because of its vitamin E, vitamin B_6 and other factors of the B complex as found in brewer's yeast and the elements potassium, sulfur, sodium, magnesium, copper, zinc, chlorine and manganese; and use of the product would insure normal functioning of the brain, eye, pituitary gland, parathyroid gland, thymus, heart, liver, gall bladder, kidneys, prostate and many other organs —[*D D. N J, F D. C. 944; October 1944.*] Also declared misbranded under the provisions of the law applicable to foods, as reported in *F. N. J. 5793.*

R & R Ultra Violet Ray and Radiation Machine—Lawndale Laboratories, Lawndale, Calif. Shipped June 29, 1942. A high voltage mercury vapor discharge tube. Misbranded because of these label misrepresentations, among others. that the device would cure or prevent arthritis, acne, asthma, gout, jaundice, carbuncles, anemia, goiter, deafness, erysipelas, locomotor ataxia, psoriasis, female trouble and many other disorders, and that it would give off ultra violet rays of adequate intensity to produce in the body vitamin D in an amount sufficient to compensate in an important respect for the deficiency of vitamin D resulting from indoor occupations and unfavorable climatic conditions, whereas the device would produce ultra violet rays of only weak intensity and supply little, if any, vitamin D to the body.—[*D. D. N. J., F. D. C. 981, November 1944.*]

Vitaminerals.—Vitaminerals Company, Los Angeles. Shipped between May 5 and 27, 1942. Consignment comprised quantities of Vitaminerals VM 1, 1+, 100 and 120 The first two contained various plant materials, the third, minerals, and the fourth, sulfates of iron and aluminum, with glycerin and water Misbranded because of label misrepresentations that No 1 would help arthritis, colds, hemorrhoids, neuralgia, neurosis, obesity and tonsillitis; No 1+, most of the same disorders and a few more; No 100, female complaints, and No 120, colonic, ear and throat troubles, anemia, asthma and many other conditions —[*D D N. J, F. D. C. 946, October 1944*] Under *D D. N. J. 1041*, issued in March 1945, Vitaminerals VM Nos 1, 100, 120 and 150 and 204 Pneumatic Dilator (a device sold for rectal disorders) were declared misbranded because of label misrepresentation

NOCTURNAL GASTRIC SECRETION IN DUODENAL ULCER

To the Editor:—In the paper on "Nocturnal Gastric Secretion in Duodenal Ulcer" by Sandweiss and others in THE JOURNAL, February 2, the following data were presented:

1. Both normal persons and patients with duodenal ulcer secrete acid gastric juice during the night of approximately the same hydrochloric acid concentration following 6 p. m. meals.

2. Under the same conditions as 1 the volume of the gastric juice obtained by continuous suction is approximately the same.

3. When intermittent single aspirations are performed, duodenal ulcer patients have a greater volume of gastric juice than normal persons, whereby it is shown that this increased volume is not caused by hypersecretion but by delayed emptying.

It seems that so wedded is the mind of gastroenterologists to the importance of hypersecretion and increased hydrochloric acid in duodenal ulcer that quite other evidence is discussed by them as though it supported their attitude. Thus in the discussion following the paper Dr. Walter C. Alvarez says:

> Sandweiss and his associates have confirmed the fact that the person with ulcer tends to go on secreting after his stomach is emptied for the night.

But apparently this happened to their normal controls too. Obviously in this respect, then, no special characteristic behavior of the ulcer patient has been shown. Dr. Burrill B. Crohn says:

> The important conclusion from this paper is the necessity for the treatment during the night by some means . . . to obtain a neutralization of the night secretion in the ulcer cases.

Since the night secretion in ulcer cases did not differ from that in the normal controls, the question naturally arises Why treat normal conditions?

Dr. A. C. Ivy says:

> However, we find, as others, that some asymptomatic subjects secrete as much interdigestive secretion as patients with an active duodenal ulcer. Thus the factor which I suspect caused the observations of those authors to be somewhat out of line with those of others is that the ulcer in their patients was relatively inactive.

If I understand English, I should say that the second of Dr. Ivy's sentences is a perfect *non sequitur.* He continues further:

> Since it has in my opinion been established that free acidity is one of the chronicity factors in peptic ulcer, the authors are justified in calling attention to the significance of the "night secretion" especially in that group of patients who tend to be refractory to management.

To a nongastroenterologist, this paper shows delayed emptying of the gastric contents to be the distinctive feature in the ulcer cases. It is entirely illogical to use this observation in support of the importance of hypersecretion and hyperchlorhydria

Apparently it is difficult to allow a new observation to change the pattern of our accustomed thought.

ALICE R. BERNHEIM, M.D., New York

MALARIA IN ST. LOUIS AREA

To the Editor:—The following observation regarding tropical types of malaria transplanted to the St. Louis area may be of some interest:

I was a resident in the St. Louis City Hospital from June 1904 to June 1910. The St. Louis World's Fair held in 1904 attracted many visitors from all parts of the world. Many came from tropical and subtropical countries and islands. Many of these tropical visitors were residents in the various concessions at the fair for about seven months in 1904.

Our local mosquitoes naturally became carriers for almost all types of malaria. Before 1904 our City Hospital records showed an average admission of 1 to 3 malaria patients daily during the summer and fall months. During 1904 quite a number of malaria patients, residents at the fair, from the tropics were admitted to the hospital, suffering from estivoautumnal and other tropical types of malaria. Local residents during this season were not much affected. During the late spring, summer and fall of 1905, however, we frequently averaged 25 to 35 or more malaria patients daily, mostly residents of our local territory. These persons were suffering from all types of malaria, and during this period 7 were admitted suffering from so-called congestive chills or malignant malaria and died within a few hours or two to three days after admission.

During the malaria season of 1906 the malaria admission rate dropped to less than one third of 1905, and after 1907 the normal average of before 1904 was struck and maintained.

I have not had time to compile exact statistics. This might prove to be an interesting research, but the figures cited are approximately correct.

CLEVELAND H. SHUTT, M.D., St. Louis.

BLOOD GROUPING

To the Editor:—In THE JOURNAL, January 12, Dr. James D. Edgar directs attention to what he justifiably suspects is an error in my article (THE JOURNAL, Nov. 17, 1945, p. 801) in reporting the infant of a mother of blood group AB as belonging to group O. This erroneous report resulted from the blood type determination having been made in the early newborn period before the blood group characteristics were adequately established. It seems improbable that there was sufficient transfused blood of group O present in this infant's circulation to have contributed significantly to this erroneous result. When the blood was again checked at the approximate age of 7 months it was found to be of blood group B. The theory of Bernstein thus remains unchallenged. Regrettably because this infant's ABO blood type had no direct relationship to the essential thesis of the paper, the laboratory report of this finding did not receive sufficiently critical attention.

CLIFFORD H. HARVILLE, M.D., Warsaw, N. Y.

RETROGRADE INJECTION

To the Editor:—The term "retrograde injection," when it is used with reference to varicose veins, is ambiguous. The ambiguity arises from the fact that the flow of blood in varicose veins is reversed (Trendelenburg positive). Consequently a type of injection which, if made into a normal vein, would be properly designated "retrograde" (against the normal direction of flow) could not be so designated if the injection should be made into a varicose vein in which the flow was reversed. However, I doubt if authors or readers generally will keep in mind the suggested distinctions and, for clearness, I believe it will be necessary for authors who use the word "retrograde" in writing of varicose veins to explain their use of it.

FREDERICK L. SMITH, M.D., Rochester, Minn.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS
EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and the Examining Board in Specialties were published in THE JOURNAL, March 16, page 735.

BOARDS OF MEDICAL EXAMINERS

ARIZONA:* *Examination.* Phoenix, April 2-3. *Endorsement.* Phoenix, April 6. Sec., Dr. J. H. Patterson, 826 Security Bldg., Phoenix.

ARKANSAS:* *Medical.* Little Rock, June 6-7. Sec., Medical Board of the Arkansas Medical Society, Dr. L. J. Kosminsky, Texarkana. *Eclectic.* Little Rock, June 6. Sec., Dr. C. H. Young, 1415 Main St., Little Rock.

CONNECTICUT:* *Endorsement.* New Haven, March 26. Sec. to the Board, Dr. Creighton Barker, 258 Church St., New Haven.

DELAWARE: *Examination.* Dover, April 9. *Reciprocity.* Dover, April 16. Sec., Medical Council of Delaware, Dr. J. S. McDaniel, 229 S. State St., Dover.

FLORIDA:* Jacksonville, June 24-25. Sec., Dr. Harold D. Van Schaik, 2736 S.W. Seventh Ave., Miami 36.

GEORGIA: Atlanta and Augusta, March 27-28. Sec., State Examining Boards, Mr. R. C. Coleman, 111 State Capitol, Atlanta 3.

HAWAII: Honolulu, July 8-11. Sec., Dr. S. E. Doolittle, 881 S. Hotel St., Honolulu 53.

IDAHO: Boise, July 9. Dir., Bureau of Occupational Licenses, Miss Agnes Barnhart, 355 State Capitol Bldg., Boise.

ILLINOIS: *Examination.* Chicago, April 2-3. *Reciprocity.* Chicago, April 4. Supt. of Registration, Department of Registration & Education, Mr. Philip Harman, Springfield.

INDIANA: Indianapolis, April 25-27. Sec., Board of Medical Registration & Examination, Dr. W. C. Moore, 301 State House, Indianapolis 4.

IOWA:* Iowa City, March 25-27. Dir., Division of Licensure & Registration, Mr. H. W. Grefe, Capitol Bldg., Des Moines 19.

KENTUCKY: Louisville, March 25-27. Sec., State Board of Health, Dr Philip E. Blackerby, 620 S Third St., Louisville 2.

MARYLAND: *Homeopathic.* Baltimore, June 18-19. Sec., Dr. J. A. Evans, 612 W. 40th St., Baltimore.

MICHIGAN:* Detroit, March 26-28. Sec., Board of Registration in Medicine, Dr. J. E. McIntyre, 100 W. Allegan St., Lansing 8.

MINNESOTA:* March 26 and April 16. Sec., Dr. J. F. Du Bois, 230 Lowry Medical Arts Bldg., St. Paul 2.

MISSISSIPPI: June. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson 113.

MONTANA: Helena, April 1-3. Sec., Dr. O. G. Klein, First National Bank Bldg., Helena.

NEBRASKA:* Omaha, March 25-27. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, 1009 State Capitol Bldg., Lincoln 9.

NEVADA: Carson City, May 6. Sec., Dr. G. H. Ross, 215 N. Carson St., Carson City.

NEW JERSEY Trenton, June 18-19. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

NEW MEXICO:* Santa Fe, April 8-9. Sec., Dr. LeGrand Ward, 141 Palace Ave., Santa Fe.

NEW YORK: Albany, Buffalo, New York and Syracuse, June 24-27. Sec., Dr. Jacob L. Lochner, Education Bldg., Albany.

NORTH CAROLINA: Raleigh, March 25-28. Act. Sec., Mrs. Louise J. McNeill, 226 Hillsboro St., Raleigh.

NORTH DAKOTA: Grand Forks, July 2-5. Sec., Dr. G. M. Williamson, 4½ S. Third St., Grand Forks.

OREGON:* *Endorsement.* Portland, April 27. *Examination.* Portland, July 24-26. Exec. Sec., Miss Lorienne M. Conlee, 608 Failing Bldg., Portland 4.

PENNSYLVANIA: Philadelphia and Pittsburgh, April. Act. Sec., Bureau of Professional Licensing [illegible] Mrs. M. G. Steiner, 351 Education

RHODE ISLAND: Prov [illegible] f Examiners, Mr. Thomas B. Casey, 3

SOUTH DAKOTA:* Pi [illegible] ensure, State Board of Health, Dr. G

TENNESSEE:* Memph[illegible] Sec., Dr. H. W. Qualls, 130 Madison Ave., Memphis 3.

TEXAS: Austin, March 27-29. Sec., Dr. T. J. Crowe, 918-20 Texas Bank Bldg., Dallas 2

VERMONT: Burlington, March or April. Sec., Dr. F. J. Lawliss, Richford.

VIRGINIA:* Richmond, March 25-28. Sec., Dr. J. W. Preston, 803 Medical Arts Bldg., Roanoke.

WASHINGTON:* Seattle, July 11-12. Sec., Department of Licenses, Miss Nell Adams, Olympia.

WEST VIRGINIA: Charleston, April 1-3. Commissioner, Public Health Council, Dr. John E. Offner, State Capitol, Charleston 5.

---

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

ARKANSAS: Little Rock, May 1. Sec., Mr. L. E. Gebauer, 701 Main St., Little Rock.

DISTRICT OF COLUMBIA: Washington, April 22-23. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6150 E. Municipal Bldg., Washington 1.

FLORIDA: Gainesville, June 4. Final date for filing application is May 20. Sec. Dr. J. F. Conn, John B. Stetson University, DeLand.

IOWA: Des Moines, April 9. Dir., Division of Licensure & Registration, Mr. H. W. Grefe, Capitol Bldg., Des Moines 19.

MICHIGAN: Ann Arbor and Detroit, May 10-11. Sec., Miss Eloise LeBeau, 101 N. Walnut St., Lansing.

MINNESOTA: Minneapolis, April 2-3. Sec., Dr. Raymond N. Bieter, 126 Millard Hall, University of Minnesota, Minneapolis 14.

NEBRASKA: Omaha, May 7-8. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, 1009 State Capitol Bldg., Lincoln 9.

TENNESSEE: Memphis and Nashville, March 25-26. Sec., Dr. O. W. Hyman, 874 Union Ave., Memphis.

WISCONSIN: Madison, April 6. Prof. R. N. Bauer, 152 W. Wisconsin Ave., Milwaukee 3.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Hospitals for Profit: Hospital Liable for Burns Caused by Patient Spilling Hot Water on Herself.—The plaintiff sued for injuries alleged to have resulted from the negligence of certain employees of the defendant hospital during the time she was a patient therein. The jury found for the plaintiff, but the trial court entered judgment for the defendant notwithstanding such verdict. From such judgment the plaintiff appealed to the Supreme Court of California.

It appeared from the evidence that the plaintiff, a woman about 60 years old, on recommendation of her physician entered the defendant hospital to have her uterus removed. The operation, which took about two hours and severely taxed the plaintiff's strength, was performed on a Saturday morning. At noon on Monday a nurse took a pot of hot water, a cup and saucer, a spoon and a tea bag into the plaintiff's room and placed them on a low table beside the bed. The plaintiff was drowsy and suffering from pain, had a tube through her nose into her stomach and had not yet recovered from the effects of $\frac{1}{6}$ grain of morphine administered about 2:50 that morning and $\frac{1}{3}$ grain of pantopon, an opium derivative, administered about 10 that morning. She said she recalled seeing some one in the room and that the person said something, but she didn't know what was said and made no reply that she remembered. A few minutes later she felt a terrific heat on her arm and chest. She screamed and nurses came in and found she had been burned. The head nurse applied some salve and bandaged the area. The nurse who took the tray into the room testified that she had not advised the plaintiff that the water was hot but had told her that she should have a nurse help her. No drinking tube was furnished. The plaintiff had had no oral nourishment since the operation except a cup of tea on the previous day.

The defendant first contended that there was no evidence of negligence on its part. It argued that the evidence furnished by doctors, nurses and the hospital chart all showed that the plaintiff was in good condition prior to the accident, that she was exceptionally alert mentally and that the drugs administered were for pain alone and would not cause mental sluggishness or drowsiness. The plaintiff's physician testified, however, that morphine usually does produce some drowsiness, more in some persons than in others, and that a person would continue to feel the effects of the drugs administered to plaintiff for about four hours. A private hospital, said the Supreme Court, owes its patients the duty of protection and must exercise such reasonable care toward a patient as his condition may require. A hospital is liable for want of ordinary care, whether from incompetency of a nurse or failure in duty by a fully qualified nurse. The duty of care extends to safeguarding the patient from self-inflicted injuries due to mental incapacity, but no one is required to guard against, or take measures to avert, that which a reasonable person under the circumstances would not anticipate as likely to happen. In the light of that standard, said the court, there was sufficient evidence from which the jury could have found that the defendant had been negligent. It could have found that the plaintiff was far from alert mentally—that her comprehension, awareness and ability to function were subnormal. It could also have found that the hospital should have been aware of that condition, since it assumed the duty of properly caring for its patients and of taking appropriate precautions. In her weakened condition and confused state of mind, said the court, it was not at all improbable that the plaintiff in one manner or another would spill the hot water on herself. She may have assumed, as a person of ordinary prudence, in a half-conscious fashion, that it was safe to attempt to consume the tea, not realizing the danger incident thereto or the extent of her weakness. According to the defendant's evidence the plaintiff had had no oral nourishment since the operation except tea on the day previous. The jury could have inferred that she would thus have a craving for the tea and might underestimate her strength and ability to handle the hot water. The defendant was under a duty to observe and know the condition of its patients. The court therefore concluded that the evidence warranted the jury in finding for the plaintiff and that there was no contributory negligence on her part.

The defendant also contended that if any one was liable it was the plaintiff's physician who gave the order that the plaintiff be served tea, knowing the customary manner in which it would be, and was, served. If the duty of care resting on the hospital embraced the serving of the tea, said the Supreme Court, it cannot escape responsibility for the performance of that duty by attempting to shift it to the doctor. Even if the doctor ordered the tea to be served in the customary manner, and that manner was negligent, the defendant would be liable in following such instruction where a duty of care toward the patient rested on it. The defendant was bound to supply proper attendance and care to plaintiff, and that duty extended to furnishing nourishment. It cannot be said that, because the doctor ordered tea to be served plaintiff, he was making the server of the tea his servant and employee to the exclusion of the defendant hospital as the employer. The hospital still had direction and control over its employees and was responsible for the care to be observed by them. Accordingly the judgment for the defendant was reversed and the trial court ordered to enter judgment for the plaintiff on the verdict.—*Rice v. California Lutheran Hospital et al., 163 P. (2d) 860 (Calif., 1945).*

Medical Practice Acts: Unlawful Sale of Morphine Sulfate Held to Be Felony Justifying Revocation of License to Practice Medicine.—This is an action to review a determination of the Board of Regents of the University of the State of New York which revoked petitioner's license to practice medicine because of conviction of a felony. From an order confirming the revocation he appealed to the Supreme Court, appellate division, third department, New York.

Petitioner pleaded guilty in the United States district court to the crime of "unlawful sales of morphine sulfate," a violation of the Harrison narcotic act. There were two counts to the indictment, he was sentenced to one year and one day on each count, sentence was suspended and he was placed on probation for two years. Shortly thereafter the State Department of Education advised him that his license to practice medicine was subject to revocation because the offense to which he pleaded guilty was a felony. Petitioner contended that the offense was a misdemeanor, not a felony, and be petitioned the district court to amend the judgment of conviction to specify the exact unlawful acts. The petition was granted and the following statement was attached to the judgment:

> The sales charged in the indictment in counts 1 & 2 consisted of the following as a matter of fact: that on two different occasions defendant, a licensed physician, did, for a consideration, issue an order or prescription for morphine sulfate not in the regular course of his practice but to an addict for a prohibited use, although the prescription was filled by a druggist who acted in good faith without knowledge that the prescription was unlawfully used.

The designation of the offense as "unlawful sale of morphine sulfate" was not changed. Respondent still insisted that the petitioner was guilty of a felony and the order of revocation followed.

Section 1264 of the Education Law provides:

> 1. Whenever any practitioner of medicine shall be convicted of a felony . . . the registration of the person so convicted may be annulled and his license revoked by the department. . . .

Section 1251 provides:

> . . . The conviction of felony shall be the conviction of any offense which if committed within the state of New York could constitute a felony under the laws thereof. . . .

Section 1751 of the Penal Law provides:

> . . . who shall peddle, sell, barter or exchange any narcotic drug, as defined in section four hundred twenty-one of the public health law, in violation of article twenty-two of such law, shall be guilty of a felony. . . .

The court said that the offense to which the petitioner pleaded guilty was a felony under the laws of the national and state governments. Petitioner's crime was completed when he unlawfully issued the prescription. The issuance of the prescription, concluded the court, constitutes a sale within the meaning of the statutes. Accordingly the determination of the Board of Regents was affirmed.—*Tonis v. Board of Regents of University of State of New York, 58 N. Y. S. (2d) 766 (N. Y., 1945).*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1936 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them

Titles marked with an asterisk (*) are abstracted below.

Silicosis.—Dayman reports observations on 116 patients with silicosis, 33 of whom came to necropsy. Thirty of the 116 patients who did not present evidence of clinical tuberculosis are divided into two groups: those with simple nodular silicosis (15 cases) and those with simple conglomerate silicosis (15 cases). The majority of the 15 patients with simple nodular silicosis were free of symptoms A few noted slight dyspnea on exercise The diagnosis was established solely on a history of prolonged exposure to silica dust and the minute, widely distributed shadows in the roentgenogram The patients with simple conglomerate silicosis exhibited symptoms and signs of pulmonary emphysema. Dyspnea was often the sole outstanding complaint. In 7 of the 15 cases massive shadows were situated symmetrically in either lung field at the hilar level, while in 8 cases the principal shadows were somewhat smaller, more numerous and irregularly distributed. In 12 there were additional minute disseminated shadows compatible with silicotic nodulation. In 77 of the 116 patients with silicosis, complicating tuberculosis existed. The symptoms were predominantly those of the tuberculous disease. The constitutional reaction is not so pronounced when tuberculosis complicates silicosis as when tuberculosis alone is present. The chest roentgenogram presented widespread minute shadows similar to those observed in simple nodular silicosis together with larger mottled shadows, the latter usually being due to the intimately combined lesions of silicosis and tuberculosis. The presence of silicosis evidently predisposes the patient to progressive tuberculosis. Sixty-six of the 77 died.

Bed Rest in Pulmonary Tuberculosis.—Bray believes that rest in bed is essential in the treatment of pulmonary tuberculosis when manifest symptoms are present. The published results achieved by strict bed rest are few in number and not convincing. A series of 67 ambulant patients was observed who presented an "early" lesion. In this series of 67 ambulant patients the results were favorable in 57 instances, questionable in 2 and unfavorable in the remaining 8. The results are comparable to those obtained by the use of strict bed rest. An additional study was made of 360 patients with incipient tuberculous disease admitted to Ray Brook during the years 1939 to 1942 inclusive; 97 patients in this group had received four months of strict bed rest before coming to Ray Brook. The remaining 263 were ambulant previous to and during their residence at the sanatorium except in a relatively few instances in which an exacerbation of the disease occurred subsequent to their admission. The results of treatment in these two groups of patients who received approximately the same period of treatment at Ray Brook were for all practical purposes identical, indicating that the initial months of treatment by strict bed rest did not appreciably alter the course of the disease.

Regional Nerve Block Anesthesia. J. R. Bone —p 612.

Amphetamine Sulfate for Respiratory Depression Caused by Morphine.—Handley and Ensberg compare the effectiveness of amphetamine with ephedrine, metrazol, caffeine and nikethamide. Their studies on 14 human subjects indicate that amphetamine sulfate is the most effective drug of the five stimulants studied in antagonizing morphine respiratory depression. Amphetamine is also more prompt in acting than the other four agents. The average percentage increases in minute volume above depressed levels were amphetamine 102, nikethamide 37, ephedrine 30, metrazol 21 and caffeine 17.

Hypobaric Pontocaine in Spinal Anesthesia.—Lund and Cameron point out that hypobaric solution of pontocaine has several disadvantages, chief among them being that the head and/or shoulders must be elevated at least fifteen to twenty minutes until the drug is fixed by the nerve tissues. They describe a technic which they have developed using hypobaric pontocaine in a 0.1 per cent solution. As it has a specific gravity of 1 001, while that of nupercaine is 1 003 and that of the spinal fluid approximately 1 007, the solution is readily controlled by gravity and the low concentration should add a wide margin of safety. Hypobaric pontocaine can be used to advantage in all cases suitable for spinal anesthesia which require under two to two and one-half hours of operating time. There were no severe postoperative sequelae in 175 cases. The advantages of the method include the ability to maintain the Trendelenburg or lateral Trendelenburg position throughout and thus aid in the prevention of shock and cerebral anoxia. The smaller dosage insures minimal interference with vital processes, favors minimum depression, accounts for decreased postoperative discomfort and sequelae and decreases the incidence of reactions and toxicity. The onset of anesthesia is probably more rapid than with other spinal anesthetic agents.

Wright.—p. 1056.

Hanger Cephalin Cholesterol and Maclagan Thymol Turbidity Tests.—Watson and Rappaport compared the Hanger cephalin cholesterol flocculation test and the Maclagan thymol turbidity test on 252 blood serums from 145 persons. Thirty-one of these subjects were believed to be normal, while 60 (154 tests) had infectious hepatitis. The underlying mechanism of the 2 tests is not identical and the Maclagan test cannot be used interchangeably with the Hanger test or as a complete substitute for it. Because of its simplicity, stability of reagents and rapidity, the Maclagan test can be used to advantage for serial observations when the diagnosis has been established, as for instance in infectious hepatitis. The Maclagan test can also be used to advantage in the differential diagnosis of jaundice or liver disease as long as its limitations are recognized. The present study indicates that a strongly positive test is just as indicative of liver injury or disease as is the Hanger test and that it may prove to be more uniformly negative in cases of jaundice due to biliary tract cancer and in cases of hepatic cancer with or without jaundice. Conversely it appears that the Hanger test is more often positive in cases of cirrhosis or subacute atrophy.

Effect of High Spinal Anesthesia on Blood Pressure of Patients with Hypertension.—Gregory and Levin found that decreases in blood pressure obtained during spinal anesthesia in patients with essential hypertension and uremia may be substantial and as great as drops in blood pressure similarly produced in patients with essential hypertension and normal renal function. The authors believe that the great fall in blood pressure induced by high spinal anesthesia indicates that the elevation of blood pressure is due to increased vasomotor tonus even in patients with extreme irreversible arteriolar disease as shown by clinical and chemical evidence of uremia. These results are contradictory to the thesis that the fall of blood pressure in hypertension produced by functional or anatomic interruption of the sympathetic nervous system is due to improvement in renal blood flow.

Synthetic Lactobacillus Casei Factor as Anti-Pernicious Anemia Substance.—Clinical and hematologic remissions were induced by Moore and his associates in 2 patients with addisonian pernicious anemia by the daily oral administration for ten days of 30 mg. and of 100 mg. of synthetic Lactobacillus casei factor ("folic acid"). One patient with macrocytic anemia of nontropical sprue and 1 patient with pernicious anemia of pregnancy responded in a similar manner when given daily 20 mg. of the preparation intravenously. These results indicate that the L. casei factor possesses anti-pernicious anemia factor activity. It is pointed out, however, that the material must be proved effective parenterally in much smaller doses and over a much longer period before it can be accepted as being closely similar in action to (or identical with) the effective principle present in liver extracts.

Analyses of Calculi in Rats.—Benjamin and his associates employed microchemical, spectrographic and optical methods in the analysis of experimentally produced bladder and urethral calculi in rats. Magnesium ammonium phosphate hexahydrate was the principal constituent, although small amounts of calcium phosphate were generally found. The calculi contained very small amounts of citrate. Spectrographic studies confirmed the presence of magnesium and phosphate and indicated the occasional presence of small amounts of sodium, iron, aluminum and silicon. Study by optical and chemical methods suggested the presence of carbonate apatite.

Treatment of Orchitis of Mumps.—Burhans thinks that orchitis of mumps is a misnomer. In examining cases of this type in a naval hospital he found that they do not develop primarily an orchitis of mumps but an acute hydrocele around a testis which causes a strangulation of the testis, in contradistinction to a slow forming hydrocele This acute process causes strangulation, acute inflammatory edema and ultimate fibrosis and atrophy of the testes. If a small scrotal incision is made during the acute orchitis, it is found that the fluid in the tunica vaginalis is under extreme pressure and has yellowish viscidity. If drainage is accomplished at this time, further therapeutic measures are not needed and the temperature curve simulates a crisis of pneumonia. In late cases the author recommends incision of the tunica vaginalis, tunica propria and tunica albuginea with drainage.

Penicillin Aerosolization in Serious Respiratory Infections.—This report by Segal and Ryder is a preliminary study of the use of aerosolized penicillin solutions in the treatment of patients with pneumonia, bronchiectasis, lung abscess and infective bronchial asthma. Twenty-one patients were treated. The clinical course of 6 patients with infective bronchial asthma was not altered, although the penicillin susceptible organisms were eradicated. Clinical cures were obtained in 5 patients with pneumococcic pneumonia and in 1 patient with an acute pulmonary infarction and pneumonitis. Penicillin blood levels of 0 028 to 0.055 Oxford unit per cubic centimeter were obtained in 5 patients. Five patients with bronchiectasis were successfully treated, 2 patients before lobectomy and the other 3 entirely medically. Such therapy is believed to be more helpful than sulfonamides or penicillin parenterally in bronchiectasis. Four patients with lung abscess were treated with penicillin aerosol. One of them, with a fulminating putrid lung abscess, died on the fifth hospital day following operation. Another, with a chronic putrid lung abscess, was adequately prepared for lobectomy. The third patient, with a large, nonodoriferous, aerobic type of lung abscess, with a fluid level, was entirely cured after six weeks of therapy. The fourth patient, with multiple lung infarcts and a lung abscess, improved slowly but completely. Penicillin aerosolization has a definite value in the treatment of patients with serious respiratory disease.

Medical Service Bureau an Answer to Socialized Medicine J. P. Neal —p 297.

Toxoplasmic Encephalitis.—Dow presents the histories of 2 patients with toxoplasmic encephalitis. The first was a child aged 2 who exhibited all the clinical manifestations of toxoplasmic encephalitis, including (1) healed or inactive chorioretinitis, (2) reduced vision, (3) strabismus nystagmus and microphthalmos, (4) intracerebral calcification, (5) one convulsive seizure, (6) internal hydrocephalus from a block at the aqueduct of Sylvius, (7) retarded speech development and (8) mental deficiency. The case was complicated by the presence of a postoperative Staphylococcus aureus meningitis and wound infection. The serologic tests for toxoplasma had not been done, and attempts to infect laboratory animals with spinal fluid were unsuccessful. The second patient, a girl aged 5, exhibited many of the signs and symptoms of toxoplasmic encephalitis. Treatment with sulfapyridine was tried and continued for ten days, maintaining a blood level of 5 to 10 mg. per cent. She seemed much improved for three weeks, but then seizures recurred. This observation and the results obtained in laboratory animals make it desirable to continue the use of sulfonamides whenever a diagnosis of toxoplasmic encephalitis is made and when there trolled by gravity and the low concentration should add a wide margin of safety. Hypobaric pontocaine can be used to advantage in all cases suitable for spinal anesthesia which require under two to two and one-half hours of operating time. There were no severe postoperative sequelae in 175 cases. The advantages of the method include the ability to maintain the Trendelenburg or lateral Trendelenburg position throughout and thus aid in the prevention of shock and cerebral anoxia. The smaller dosage insures minimal interference with vital processes, favors minimum depression, accounts for decreased postoperative discomfort and sequelae and decreases the incidence of reactions and toxicity. The onset of anesthesia is probably more rapid than with other spinal anesthetic agents.

Hanger Cephalin Cholesterol and Maclagan Thymol Turbidity Tests.—Watson and Rappaport compared the Hanger cephalin cholesterol flocculation test and the Maclagan thymol turbidity test on 252 blood serums from 145 persons. Thirty-one of these subjects were believed to be normal, while 60 (154 tests) had infectious hepatitis. The underlying mechanism of the 2 tests is not identical and the Maclagan test cannot be used interchangeably with the Hanger test or as a complete substitute for it. Because of its simplicity, stability of reagents and rapidity, the Maclagan test can be used to advantage for serial observations when the diagnosis has been established, as for instance in infectious hepatitis. The Maclagan test can also be used to advantage in the differential diagnosis of jaundice or liver disease as long as its limitations are recognized. The present study indicates that a strongly positive test is just as indicative of liver injury or disease as is the Hanger test and that it may prove to be more uniformly negative in cases of jaundice due to biliary tract cancer and in cases of hepatic cancer with or without jaundice. Conversely it appears that the Hanger test is more often positive in cases of cirrhosis or subacute atrophy.

Effect of High Spinal Anesthesia on Blood Pressure of Patients with Hypertension.—Gregory and Levin found that decreases in blood pressure obtained during spinal anesthesia in patients with essential hypertension and uremia may be substantial and as great as drops in blood pressure similarly produced in patients with essential hypertension and normal renal function. The authors believe that the great fall in blood pressure induced by high spinal anesthesia indicates that the elevation of blood pressure is due to increased vasomotor tonus even in patients with extreme irreversible arteriolar disease as shown by clinical and chemical evidence of uremia. These results are contradictory to the thesis that the fall of blood pressure in hypertension produced by functional or anatomic interruption of the sympathetic nervous system is due to improvement in renal blood flow.

Synthetic Lactobacillus Casei Factor as Anti-Pernicious Anemia Substance.—Clinical and hematologic remissions were induced by Moore and his associates in 2 patients with addisonian pernicious anemia by the daily oral administration for ten days of 30 mg. and of 100 mg. of synthetic Lactobacillus casei factor ("folic acid"). One patient with macrocytic anemia of nontropical sprue and 1 patient with pernicious anemia of pregnancy responded in a similar manner when given daily 20 mg. of the preparation intravenously. These results indicate that the L. casei factor possesses anti-pernicious anemia factor activity. It is pointed out, however, that the material must be proved effective parenterally in much smaller doses and over a much longer period before it can be accepted as being closely similar in action to (or identical with) the effective principle present in liver extracts.

Analyses of Calculi in Rats.—Benjamin and his associates employed microchemical, spectrographic and optical methods in the analysis of experimentally produced bladder and urethral calculi in rats Magnesium ammonium phosphate hexahydrate was the principal constituent, although small amounts of calcium phosphate were generally found. The calculi contained very small amounts of citrate. Spectrographic studies confirmed the presence of magnesium and phosphate and indicated the occasional presence of small amounts of sodium, iron, aluminum and silicon. Study by optical and chemical methods suggested the presence of carbonate apatite.

Treatment of Orchitis of Mumps.—Burhans thinks that orchitis of mumps is a misnomer. In examining cases of this type in a naval hospital he found that they do not develop primarily an orchitis of mumps but an acute hydrocele around a testis which causes a strangulation of the testis, in contradistinction to a slow forming hydrocele. This acute process causes strangulation, acute inflammatory edema and ultimate fibrosis and atrophy of the testes. If a small scrotal incision is made during the acute orchitis, it is found that the fluid in the tunica vaginalis is under extreme pressure and has yellowish viscidity. If drainage is accomplished at this time, further therapeutic measures are not needed and the temperature curve simulates a crisis of pneumonia. In late cases the author recommends incision of the tunica vaginalis, tunica propria and tunica albuginea with drainage.

Penicillin Aerosolization in Serious Respiratory Infections.—This report by Segal and Ryder is a preliminary study of the use of aerosolized penicillin solutions in the treatment of patients with pneumonia, bronchiectasis, lung abscess and infective bronchial asthma. Twenty-one patients were treated. The clinical course of 6 patients with infective bronchial asthma was not altered, although the penicillin susceptible organisms were eradicated. Clinical cures were obtained in 5 patients with pneumococcic pneumonia and in 1 patient with an acute pulmonary infarction and pneumonitis. Penicillin blood levels of 0 028 to 0.055 Oxford unit per cubic centimeter were obtained in 5 patients Five patients with bronchiectasis were successfully treated, 2 patients before lobectomy and the other 3 entirely medically. Such therapy is believed to be more helpful than sulfonamides or penicillin parenterally in bronchiectasis. Four patients with lung abscess were treated with penicillin aerosol. One of them, with a fulminating putrid lung abscess, died on the fifth hospital day following operation. Another, with a chronic putrid lung abscess, was adequately prepared for lobectomy. The third patient, with a large, nonodoriferous, aerobic type of lung abscess, with a fluid level, was entirely cured after six weeks of therapy. The fourth patient, with multiple lung infarcts and a lung abscess, improved slowly but completely. Penicillin aerosolization has a definite value in the treatment of patients with serious respiratory disease.

Toxoplasmic Encephalitis.—Dow presents the histories of 2 patients with toxoplasmic encephalitis The first was a child aged 2 who exhibited all the clinical manifestations of toxoplasmic encephalitis, including (1) healed or inactive chorioretinitis, (2) reduced vision, (3) strabismus nystagmus and microphthalmos, (4) intracerebral calcification, (5) one convulsive seizure, (6) internal hydrocephalus from a block at the aqueduct of Sylvius, (7) retarded speech development and (8) mental deficiency. The case was complicated by the presence of a postoperative Staphylococcus aureus meningitis and wound infection. The serologic tests for toxoplasma had not been done, and attempts to infect laboratory animals with spinal fluid were unsuccessful. The second patient, a girl aged 5, exhibited many of the signs and symptoms of toxoplasmic encephalitis. Treatment with sulfapyridine was tried and continued for ten days, maintaining a blood level of 5 to 10 mg. per cent. She seemed much improved for three weeks, but then seizures recurred. This observation and the results obtained in laboratory animals make it desirable to continue the use of sulfonamides whenever a diagnosis of toxoplasmic encephalitis is made and when there has not been extensive permanent cerebral damage. It is felt that the condition is more common than the reported cases would indicate and that a greater incidence will be found when knowledge of this disorder has become more generally available.

Treatment of Experimental Liver Cirrhosis.—Lowry and his associates maintained rats on a cirrhosis producing diet for sixty-three to eighty-four days, and the status of the liver of each rat was determined at that time by biopsy. The rats were then treated by the daily administration of large amounts of choline chloride or by using a diet containing large amounts of casein. The gross and microscopic appearance of the liver after treatment was compared with the biopsy findings. During the period of treatment a striking improvement in the gross and microscopic appearance of the liver occurred. Although therapy did not have a recognizable effect on the fibrous tissue present, it apparently prevented further progression of the cirrhotic process and produced improvement in the microscopic appearance of the parenchyma.

Bone Rarefaction After Skull Injuries. J. Arendt.—p. 608.

Lipiodol Intravasation During Uterosalpingography.—Eisen and Goldstein recommend certain measures which prevent intravasation or limit its extent. Injection for uterosalpingography should not be done earlier than six to eight days or later than ten days after completion of menstruation. The optimum period would seem to be eight to ten days after the menstrual period. It should not be performed in less than ten days after any operation on the uterus, in order to permit complete healing. The position of the uterus should be determined by the use of a sound. When the cannula is inserted it should be held, if necessary, at an angle that is calculated to make it parallel to the cervical canal, so that the tip of the cannula is not likely to be in contact with the endometrium. Williams recommends that the injection be done under fluoroscopic control both for ascertaining the position of the uterus and for early recognition of any intravasation. It is best to keep the pressure as low as is commensurate with proper filling of the uterus. A top pressure of 180 to 200 mm. of mercury is safe and satisfactory in practically all cases. The amount of lipiodol injected should be no more than is necessary to fill the uterus and tubes, with a slight spill. A satisfactory plan is to inject 4 to 6 cc. and maintain pressure while the film is taken and developed. If more lipiodol is required, it can be injected subsequently.

Louse Borne Relapsing Fever in Tunisia.—Greaves and his associates observed 40 patients in a special ward at the French Naval Hospital in Ferryville and considered partial data on an additional 80 cases in the village of El Haouid, 71 in the village of Hadjerine and 3,806 in the city of Tunis. They conclude that: 1. Penicillin is as effective as neoarsphenamine in the treatment of relapsing fever. It is more expensive and requires more work to administer than the arsenical, so that in the average case it offers little advantage. 2. Penicillin is probably the drug of choice in relapsing fever accompanied by jaundice. 3. The use of white mice or adult guinea pigs in experimentation on Spirocheta berbera, obtained directly from human blood, is not feasible. 4. One application of 10 per cent DDT powder, if thoroughly applied to a population, is nearly 100 per cent effective in stopping a louse borne epidemic of relapsing fever.

Physiologic Gastrectomy.—Somervell ligated most of the arterial supply of the stomach in 400 cases of gastroenterostomy for duodenal ulcer. The usual effect was an immediate and considerable drop in gastric acidity. Only 1 of the 400 patients in whom ligation had been done returned with gastrojejunal ulcer, whereas 7 of 300 gastrectomy patients returned with recurrent ulceration. In cases in which the operation of arterial ligation alone has been done without gastroenterostomy the early and late results are similar to those in which gastroenterostomy was combined with arterial ligation. It is evident that the reduction of acidity is caused by ligation of the arteries and not by the gastrojejunostomy. The author concludes that gastrovascular ligation is the operation of choice in cases of duodenal ulcer with severe hyperacidity and that it can be combined easily with gastroenterostomy without raising the mortality of the operation.

Sulfadiazine in Treatment of Malaria.—Coxon and Hayes treated 20 cases of malaria, including both fresh and relapsing cases of benign tertian, fresh and relapsing cases of malignant tertian, and 1 case of quartan malaria, with sulfadiazine alone. Ten untreated controls were used for comparison. An initial dose of 5 Gm. of sulfadiazine was employed in the majority of cases. This was followed by 1 Gm. every four hours. Patients treated with sulfadiazine had their blood cleared of parasites after an average period of twelve days from the onset of the attack and eight days after the initiation of treatment. All of the 10 untreated controls had circulating blood parasites after the same interval of time. The latest day on which a treated patient became parasite free was the seventeenth day of the disease. While all the treated men had parasite free films after seventeen days, the controls untreated for the same period had parasites present. The treated patients, except 1 with a heavy infection with malignant tertian malaria, were afebrile by the thirteenth day of the attack, while 6 of the 10 controls continued to show a high temperature after the same interval. Sulfadiazine thus exerts an antimalarial effect on the temperature and in clearing the peripheral blood of parasites, but its action is slower than that of quinine and atabrine in controlling an attack of malaria. Of the 20 men treated with sulfadiazine 15 relapsed within one month from the cessation of treatment. This fact alone rules out its usefulness in the routine treatment of malaria. In addition there is the tendency of the drug to produce renal complications. The gametocytes of Plasmodium falciparum appeared to be unaffected by the drug.

Features of Pathology in Deforming Spondylosis. O. Torgersen.—p. 2333.

Electrocardiographic Changes in Cor Pulmonale.—Examination of the electrocardiograms with special regard to the characteristic changes of cor pulmonale in 46 cases of bronchial asthma selected at random disclosed signs of right coronary insufficiency in 15 cases, in 5 cases only during attacks. Grave symptoms, such as dilatation of the right half of the heart, dilated conus pulmonale, cyanosis or edema, were present in 6 of the 15 and in only 2 of the other cases. The QRS complexes were on the whole more typical of right preponderance during attacks than in the intervals free from attacks and were most typical in the 6 cases mentioned. The proportional figures were higher in cases of right coronary insufficiency than in the others, higher during attacks than in the free intervals, highest in the 6 cases named. For greatest help from electrocardiography in asthmatic patients systematic examinations should be made during attacks and the free intervals, accompanied by determination of the blood pressure.

Hygiea

*Determination of Serum Iron and Its Practical Significance. J. Waldenström.—p. 2341.

Determination of Serum Iron and Its Practical Significance.—Waldenström says that in iron deficiency anemia a persisting low serum iron level after normalization of the hemoglobin values indicates further treatment with iron. Normal serum iron excludes iron deficiency anemia. In iron deficiency without anemia (latent sideropenia) low serum iron reveals the nature of the condition. Such cases are common after gastric operations. In pernicious anemia with normal or nearly normal blood values after liver therapy a continued low serum iron points to need of iron therapy; it may also indicate a complication such as cancer of the stomach. In atypical cases of pernicious anemia the influence of liver therapy on the serum iron value supports the diagnosis; the sudden drop in the serum iron on liver therapy is one of the earliest and most specific signs of remission. In inoperable cancer of the stomach with cachexia, improvement may result from treatment with iron. The iron tolerance test may reveal cases which will lend themselves to the treatment.

Book Notices

A Textbook of Surgery. By American Authors. Edited by Frederick Christopher, B.S., M.D., F.A.C.S., Associate Professor of Surgery, Northwestern University Medical School, Chicago. Fourth edition. Cloth. Price, $10 Pp. 1,548, with 1,483 illustrations on 762 figures. Philadelphia & London: W. B. Saunders Company, 1945.

The caliber of the contributors to this textbook of surgery is without peer in the world today. In this revision the list of contributors has been increased, the text reset to a two column formation on each page and the content expanded. The selection of men actively engaged in teaching has suppressed to a considerable extent a tendency to enlarge the subject matter to a degree of technicality beyond the capacity of the student. There is little room to disagree with the opinions rendered in the book, because of the authority behind each contributor. The inclusion of a separate section on modern chemotherapy is valuable from several points of view. It reflects the proper importance of these recent advances in surgery, it will enhance the possibilities of prompt inclusion of future progress and it should eliminate more rapidly discarded technics. The section on military surgery is still of value in that many lessons learned from the war have not as yet been fully correlated with civilian application. No one desires any other future use for this subject, but its value to posterity is still a possibility.

The position which this work will occupy in medicine is still difficult to analyze. For the student it appears to be more valuable as a reference book, and yet its concise, terse and fundamental approach makes it valuable for primary teaching of surgery. For the intern, resident and general practitioner it may be more useful. For more advanced study a bibliography has been included at the end of each section which has invariably included recent references. If the hazard "to become all things to all men" can be avoided successfully, this book will continue to be an efficient instrument of instruction in surgery.

Cleft Palate and Speech. By Muriel E. Morley, B.Sc., F.C.S.T., Speech Therapist to the Royal Victoria Infirmary, Newcastle-upon-Tyne. Fabrikold. Price, 7s. 6d. Pp. 160, with 52 illustrations. Baltimore: William Wood & Company; Edinburgh: E. & S. Livingstone, 1945.

This handbook by the speech therapist to several prominent British hospitals gives a most comprehensive view of this still difficult surgical and therapeutic problem. The text is well arranged and illustrated by line drawings, colored plates and photographs.

An introductory chapter deals with the embryologic formation of the nose, lips, alveolar rim, hard and soft palate and superior maxilla and mandible. There follows a classification of the different types of cleft lip and palate based on the embryologic derangement which causes them. There is a well illustrated description of the anatomy of the hard and soft palate, including the attached muscles with their innervation and blood supply. Chapter three provides an interesting historical account of the major developments in the surgical technic of palate repair with descriptions of the Langenbeck, Dieffenbach and Ferguson methods of median suture, the Lane flap and the Brophy compression operation. In more detail are described the Passavant plastic procedures on the pharyngeal wall, Ganzer's forerunner of the push-back technic of Dorrance, and Gillies' use of prosthetic appliances in closing defects of the hard palate. Wardill's pharyngoplasty is considered in detail, and his four-flap operation is illustrated by colored plates. Dennis Brown's two stage procedure for narrowing the nasopharynx is clearly described. In consideration of all the surgical procedures there is stressed the extreme desirability of a narrowed nasopharynx, an elongated and united soft palate, the elimination of palatal tension and the avoidance of nasal and oral scar tissue.

Subsequent chapters describe the problem of feeding in cases of cleft palate, the mechanism of normal speech development and the abnormalities in speech which result from palatal deformities. These speech abnormalities are further considered in great detail, being subdivided first according to the preoperative speech defects and secondly to the anatomic defects which cause them.

The author next considers the technic of examination of the patient prior to speech training, with attention to age, palatal anatomy and competence of the palatopharyngeal sphincter. This is followed by a detailed analysis of the common postoperative speech defects. A chapter is devoted to the subject of speech treatment and the conditions affecting its success, such as the anatomic and physiologic results, the patient's intelligence, his hearing acuity, his speech "sense" and his age, environment and personality. Further suggestions as to remedial procedures follow. The book concludes with 25 cases histories illustrative of the material previously discussed and subdivided according to the specific problem to be illustrated. A short bibliography is appended.

For the speech correctionist dealing with the problem of cleft palate, this book affords a comprehensive and well presented aid.

Lehrbuch der allgemeinen Kinderpsychiatrie einschliesslich der allgemeinen Psychiatrie der Pubertät und Adoleszenz. Von M. Tramer, Dr. med. et phil., Priv. Doz. der Universität Bern. Second edition. Cloth. Price, 32 Swiss francs. Pp. 517, with 8 illustrations. Benno Schwabe & Co., 1945.

In this edition the text has been improved and made more complete. It contains fourteen chapters, starting with an introduction of psychiatry of children and a survey of the psychologic views in child psychiatry, followed by the standard of development or evolution in the normal child, methods of investigation, foundation of general psychopathology, general etiology, various diseases, diagnosis, prognosis and treatment. There is a chapter each on social behavior and psychologic hygiene. There is an excellent chapter on 27 illustrative cases. This book should be helpful to psychiatrists.

Jobs for the Physically Handicapped. By Louise Neuschutz. With a foreword by William Rush Dunton Jr., M.D. Cloth. Price, $3. Pp. 240. New York: Bernard Ackerman, Inc., 1944.

The author combines case experiences of physically handicapped persons, with ideas for entertaining and profitable hobbies for these persons, into an interesting and informative book. The suggestions range from individual hobbies to trades such as woodworking and bookbinding; the book also covers cooking, drawing and writing. Details of practice are not given; the references, however, are adequate. The principal merit of the book lies in the interesting presentation of material and the emphasis on the opportunities available and open. This should assist in providing interest and motivation to the handicapped, with whom the great problem is often not to find tasks of which they are capable but to insure that they are motivated to do them. The book is recommended for all persons who are physically handicapped.

General Biology and Philosophy of Organism. By Ralph Stayner Lillie. Cloth. Price, $3. Pp. 215. Chicago: University of Chicago Press, 1945.

The author is well qualified to write about the subject. As stated in the preface, "this short book is an essay on theoretical biology." Mr. Lillie discusses his subject in a clear, logical, understandable manner. He demonstrates how the simple fact of evolutionary change proves that nature is not wholly stable. Evolution clearly indicates that the existence of various forms, systems and activities were at some time new. A general idea of the clarity with which he expresses himself may be obtained from a brief quotation from the summary at the end of the book: "In life processes, as experienced in ourselves, we find a foundation of stable conditions and processes which are physical; superimposed on these we find also the immediately felt quality or property which we call psychical. The latter is a matter of direct experience and is active in the present; and since present time is new (not previously existent), the psychical would appear to provide the required source of novelty." The book is well written and contains a well chosen bibliography and an adequate index.

Pastimes for the Patient. By Marguerite Ickis. Cloth. Price, $3 Pp. 285, with illustrations by Reba Selden Esh. New York: A. S. Barnes and Company, Inc., 1945.

This book, written for the use and guidance of hospital patients, will be of interest to all convalescing patients. Stimulating hobbies and games are described in detail and are well illustrated. Certain of the pastimes, such as photography, are rather ambitious undertakings for the patient. The printing is somewhat small, but it is readable and the book can be recommended.

Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

NICOTINE CONTENT OF SMOKE FROM CIGARS AND CIGARETS

To the Editor:—Can you give me the comparable effect on the heart of a normal man aged 50 between smoking approximately thirty cigarets a day (inhaling) and six or seven cigars a day (not inhaling).

M.D., Missouri.

Answer.—Thirty cigarets, weighing about 1 Gm. apiece and containing about 2 per cent nicotine in the tobacco, might contain just about the same amount of nicotine as six cigars weighing about 5 Gm. apiece and with the same nicotine content. About one fourth of the nicotine content of the tobacco may be expected to appear in the puffed smoke, though this figure may vary greatly, depending on the manner of smoking. Several writers have reported that a higher proportion would appear in cigar than in cigaret smoke. Only about 12 per cent of the nicotine escapes with the exhaled smoke after inhalation, as compared to about 33 per cent after simple puffing without inhalation, but in either case the bulk of the nicotine appears to be deposited in the mouth or air passages. Accordingly, it might be possible for the thirty cigarets inhaled to yield about the same amount of nicotine absorption as the six cigars not inhaled—about 100 mg. of the alkaloid, which, even if distributed through fifteen hours in the day, would give a concentration of more than 6 mg. per hour, a level at which definite symptoms might be expected in an average normal person, even with moderate habituation to the alkaloid.

Since either cigarets or cigars may vary greatly in their nicotine content, however, and the latter especially may vary greatly in size, and both may be smoked at widely different rates and with the discarding of greatly different amounts of tobacco and retained constituents of the smoke in the unburned stumps, this conclusion required much caution. Moreover, much nicotine may be absorbed from the unburned stump of a cigar by the user who chews or sucks as he smokes, while on the other hand the habitual spitter may rid himself of some of the nicotine taken in by expectoration.

The nicotine discussed is the chief factor found in cigaret or cigar smoke which may be expected to affect the normal heart, with the production of changes in rate and rhythm and even in electrocardiographic patterns in some cases. Carbon monoxide in the smoke would be greater in the cigar smoke than in the cigaret smoke but rarely sufficient to produce symptoms. The same is generally true of the other constituents of tobacco smoke.

The most important experimental study of the factors discussed was that of J. Percy Baumberger (*J. Pharmacol. & Exper. Therap.* **21:**35 [Feb.] 1923).

HIRSCHSPRUNG'S DISEASE

To the Editor:—A 3 year old boy has Hirschsprung's disease. He apparently has never had a normal bowel movement, and the condition has been diagnosed on the basis of x-ray findings. He has been without bowel movements for periods of five to eleven days, at which times an oil enema has been given. He also has received syntropan. If the drug is withheld, considerable discomfort ensues. The child is on a low residue diet and is given Vi-penta pearls. A lumbar sympathectomy has been suggested at or about the age of 6. In my opinion syntropan is contraindicated, at least from a physiologic point of view.

M.D., Georgia.

Answer.—The treatment of megacolon depends on the severity of the condition and the age of the patient. Surgical resection is the procedure of choice when patients have not responded to sympathectomy or medical treatment, but it should not be undertaken if the patient is less than 5 years of age.

Medical treatment usually consists in repeated thorough emptying of the colon, administration of mecholyl bromide, neostigmine bromide or syntropan or spinal anesthesia, other parasympathetic paralyzants and sympathetic stimulants. If the condition does not respond to spinal anesthesia, sympathectomy will be of doubtful value. Sympathectomy sometimes is followed by satisfactory bowel function, but the enlarged colon rarely assumes normal proportions.

A comprehensive consideration of this problem may be found in an article by Penick in The Journal, June 9, 1945, page 423.

IMPOTENCE AFTER PROSTATECTOMY

To the Editor:—A few months ago a patient had a prostatectomy for hypertrophy. Since the operation he has been impotent and has received massages twice a week for five or six months with slight improvement. Could there have been some radical changes of the blood supply and could the blood supply be reestablished by operation? This is not a psychologic case.

W. M. Sykes, M.D., Dallas, Texas.

Answer.—After a surgical operation on the prostate gland there may develop, in a small percentage of patients, various degrees of impotence. This, however, is not caused by an interference with the blood supply to the genitalia. Therefore in this patient the cause of the impotence is not related to a disturbance of the blood supply. It is questionable whether prostatic massages will be of benefit unless there still exists an infection of the prostate gland. Likewise the use of androgen will not be of value unless the impotence is caused by a deficiency of this material. If it has not been done, a careful search should be made for some general disorder that may have a bearing on the patient's sex trouble such as anemia, syphilis or a variety of organic neurologic disorders. It is not yet determined whether a psychic disturbance may not be involved.

MARRIAGE AND PREGNANCY IN MULTIPLE SCLEROSIS

To the Editor:—A woman has multiple sclerosis, which began at the age of 14 and has progressed little up to her present age of 21. Her only symptoms are weakness of the left ankle, with occasional attacks of dizziness and headache with some fatigue. What are the odds of this condition becoming aggravated following marriage and pregnancy? I have 2 patients, men, who are married, with stationary symptoms over a ten year period of time.

M.D., New York.

Answer.—There is no evidence to date to indicate that marriage is contraindicated in a case of multiple sclerosis. When a woman who has multiple sclerosis becomes pregnant it must be admitted that the disease may become active again or increase in severity. Pregnancy, however, is not necessarily deleterious to the course of events (multiple sclerosis) and would probably be even less often so if the patient was more carefully guarded from fatigue during pregnancy. She should be given a longer rest period during the puerperium and afterward. She should not be allowed to nurse her child. It is impossible to anticipate whether the illness will become aggravated or not by a pregnancy. The patient should be informed of all the facts in the matter and then be permitted to use her own judgment.

ANGINA OF EFFORT AND HYPERCHOLESTEREMIA

To the Editor:—A white woman aged 38 has a chief complaint of severe constriction substernal pain on effort. This clears promptly on rest or glyceryl trinitrate and is apparently a typical "angina of effort" syndrome. Other than this her general health has always been good. Examination by a competent cardiologist shows a negative electrocardiogram with the heart slightly enlarged to the left by orthodiagram. Further the studies in the hospital were essentially negative except for a blood cholesterol of 460. The glucose tolerance test was normal. The Wassermann reaction was negative. On a low cholesterol diet her blood cholesterol dropped to 280 and her symptoms disappeared. As long as she watches her diet her cholesterol remains low and she is free of symptoms. If she becomes careless, her cholesterol increases and symptoms return. What could cause this type of hypercholesteremia and could you offer any suggestion, other than dietary, for treatment? The blood pressure ranges from 120/70 to 140/80.

M.D., Pennsylvania.

Answer.—The clinical history as stated is that of angina pectoris on effort, which is due to coronary atherosclerosis in the great majority of cases. Negative physical examination, electrocardiogram and x-ray studies do not rule out coronary insufficiency with angina pectoris. The high blood cholesterol content is in favor of the diagnosis and is a finding that is not at all infrequent in young patients with coronary disease and points undoubtedly to a disturbance of cholesterol metabolism as an etiologic factor in the early occurrence of coronary atherosclerosis in these cases. It is unusual for a woman under 40 to have angina pectoris, but the evidence here seems to support such a diagnosis. The fundamental cause of the hypercholesteremia and disturbed cholesterol metabolism is still a subject for future research.

Undoubtedly dietary treatment is of prime importance, especially in prevention, and it is quite likely that thyroid therapy would prove in this case, as in others, a useful preventive measure, to be carried out cautiously, however, in the face of angina pectoris.

There is no statement about the basal metabolic rate or weight. These should be followed closely. It is probable that the basal metabolic rate would be found low in this case.

POSSIBLE REINFECTION IN PATIENT TREATED FOR CONGENITAL SYPHILIS

To the Editor:—In August 1945 I was consulted by a Negro woman aged 22 who had what appeared to be a typical chancre of the lip—an annular, distinctly indurated, slightly elevated lesion with an eroded surface crusted with grayish yellow exudate; small satellite nodes were palpated at the angle of the jaw. Wassermann and Kahn tests on her blood were both negative and a diligent dark field examination was entirely fruitless. One week later the dark field and Kahn were still negative, while a doubtful Kolmer Wassermann was reported. Five days later Kahn and Wassermann reactions were both strongly positive. An injection of 0.04 Gm. of oxophenarsine hydrochloride (mapharsen) was given, and the lesion promptly improved. No secondary lesions were ever noted. However, further examination did reveal corneal opacities. These the patient attributed to an eye infection arising at the age of 11 years. She had been treated at a reputable clinic, a report from which disclosed diagnosis in 1934 of interstitial keratitis on clinical grounds supported by strongly positive serologic tests. During the ensuing five years treatment had been given in the amount of thirty injections of neoarsphenamine 0.2 Gm. and seventy injections of a bismuth preparation of unstated dosage. When the patient was last seen at this clinic in 1939, residual opacities were present and serologic tests were strongly positive. Serologic tests made on the patient at a local hospital in 1943 were negative for syphilis. The following questions arise: 1. Is this a true primary lesion, and if so does it represent an instance of superinfection? Reinfection does not seem to be likely. 2. Is it likely that a tertiary infection (gumma) would follow this behavior pattern? 3. Am I justified in outlining for this patient a regimen routine for primary cases? 4. Is there any warranty for the use of penicillin as less likely to flare up the eye situation? If I could have anticipated the technicalities in this case, I would have insisted on dark field examination of the satellite nodes. Since August the patient has received ten injections of oxophenarsine hydrochloride (0.04-0.06 Gm.) and four of bismuth subsalicylate 0.2 Gm. At the last examination (Oct. 12, 1945) the Wassermann reaction was strongly positive, the Kahn reaction was negative and the eye condition was unchanged, while faint scarring and depression could be detected at the site of the lip lesion. *Winder L. Porter, M.D., Dover, Del.*

Answer.—1. The diagnosis of extragenital primary syphilis in the case described cannot be definitely substantiated in the absence of positive dark field examination from the lesion itself or from the satellite lymph nodes. Several instances of apparently quite definite reinfection in patients treated for congenital syphilis have been reported in the literature. The most recent papers are those of R. D. Hahn (*Am. J. Syph., Gonor. & Ven. Dis.* **25**:200 [March] 1941) and S. D. Allison (*ibid.* **26**:212 [March] 1942). Four such cases are reported in these two papers, in 1 of which treatment was not begun until late in the course of the disease, although in the 3 others treatment was originally begun in infancy. Reinfection cannot be definitely differentiated from superinfection in human beings (The Changing Concept of Reinfection with Syphilis and Its Applicability as a Criterion of Cure, editorial, *ibid.* **29**:474 [Aug.] 1945).

2. It is unlikely that a gumma of the lip would behave serologically in the manner described in this case.

3. Yes.

4. There is nothing in the situation to indicate that penicillin or any other form of treatment will cause the old interstitial keratitis to flare up. Should it be desired to substitute penicillin treatment for the arsenic-bismuth chemotherapy so far given, the patient should receive a minimum of 2.4 million units of penicillin given in sixty intramuscular injections every three hours day and night over a minimum period of seven and one-half days.

ANT CONTROL IN HOSPITALS

To the Editor:—Our hospital is located at the foot of Missionary Ridge in a wooded section with considerable water drainage from the ridge. The hospital has been infested with small red ants for about two years, but the past few months the number has been even greater. Insecticides have been used as a spray, the legs of beds have been set in cans of the solution and various type of powders have been tried. The pest is a menace in every part of the hospital and nurses' home from the surgery to the basement. Are there any remedies that have been used in other communities for this insect? This certainly cannot be the only hospital that has had this problem. *Helen Esther Gillespie, Supt., Chattanooga, Tenn.*

Answer.—There are a number of different species of ants which invade hospitals and homes. The habits of these ants differ considerably, and no single formula for their control or eradication can be laid down. In fact, the same species of ant may react differently to control measures applied under varying conditions. Some ants have their nests outdoors and enter the buildings for food, while others nest in the walls or basement floors. If their nesting places can be located, the colonies can often be destroyed by applying a small amount of carbon disulfide to the holes entering the nests. The holes should then be covered with packed soil or paper held down with bricks. Carbon disulfide is explosive and inflammable and therefore should not be used near any fire. Sodium fluoride dusted along the places where the ants crawl will often get rid of them, at least temporarily. DDT sprayed freely along baseboards, window-sills and other places where the ants are seen crawling has been found effective in some cases. It is usually applied as a 5 per cent solution in odorless kerosene or as a dust (10 per cent in pyrophyllite). Care should be taken not to get sodium fluoride or DDT into food or where it can be confused with food items. Poisoned baits of several formulas have been employed successfully against ants. Three of these are as follows:

Formula 1. Dissolve 4 ounces of sugar in 1 quart of water and stir in ½ ounce of tartar emetic.

Formula 2. Dissolve ½ pound sugar in 1 pint of hot water and add 1/7 ounce (62½ grains) of sodium arsenate; bring to a slow boil and strain.

Formula 3. For ants that will not eat sweets but prefer grease and meat, work small quantities of tartar emetic into grease or pieces of bacon rind.

These baits are put out in small containers in the areas where the ants are foraging. Small tin cans with the top indented before putting on the covers or tin pill boxes with holes to admit the ants will suffice. Such poisons should be handled carefully and kept out of the reach of children.

EFFECT OF ANDROGENS ON BREAST ATROPHY

To the Editor:—In a patient 54 years old, what would be the effect of the use of androgens, testosterone propionate or methyl testosterone in causing atrophy of the breasts? *M.D., Michigan.*

Answer.—Administration of the androgens testosterone propionate or methyl testosterone will produce an atrophy of the breasts in many women if the dosage is large enough to suppress ovarian function. Such dosages would amount to 200 to 800 mg. of testosterone propionate per month. Atrophy of the breasts is the result of the neutralization of estrogens and the suppression of ovarian function following inhibition of the anterior pituitary gonadotropic hormone secretion. Androgens will cause atrophy of the breasts only through eliminating the influence of estrogen on the breasts, and as in a patient of 54 there is already an absence of estrogens due to the menopause, further atrophy would not occur following androgen therapy for relief of menopausal symptoms.

AGE FOR APPLICATION OF ORTHODONTIC APPLIANCES

To the Editor:—What is the earliest age at which orthodontic work should be begun on a child? *M.D., New York.*

Answer.—The earliest age at which orthodontic "work" should be undertaken is that time when there exists a condition which stands in the way of normal growth, development or function of the teeth and dental structures and which has little or no possibility of being corrected by further growth or developmental processes or by the institution of procedures which are simpler and less disturbing to the child.

It is seldom practical to place orthodontic appliances before the deciduous dentition is complete, although occasionally this has been done with satisfactory results. The nature of the particular problem must be the determining factor.

The correction of the condition may not prevent the occurrence of malocclusion from other causes at a later age and, in those conditions in which the malocclusion is due to discrepancies in harmonious relationships which arise from either genetic or growth and developmental causes, more than one period of orthodontic treatment may be advisable. Treatment in the early years in these instances is for the purpose of obtaining ma-
mum functional contribution to the growth and d
potentialities possessed by the child.

TESTS FOR T

SURGICAL MANAGEMENT OF ACUTE ARTERIAL OCCLUSION

COMMANDER GERALD H. PRATT, MC(S), U.S.N.R.
New York

There is no greater emergency in surgery than that caused by the closure of a major artery with immediate loss of circulation of the parts supplied by that artery. Unless that circulation is restored either by opening the occluded vessel or by adequate collateral circulation, death of the part is inevitable and in immediate prospect. Medical management has to do with stimulating and attempting to develop collateral circulation. We are interested in that too from a surgical standpoint, but our primary interest is to reestablish the function of that particular vessel. Surgical methods to relieve arterial occlusion, as well as means of stimulating collateral circulation, will be discussed in relation to the causes of acute arterial closure. When the major vessel is occluded, it and its collateral circulation go into a spasm. This is nature's protective mechanism, one of shock to reduce hemorrhage and to prevent clotting in the vessels which will be required for the collateral circulation. Efforts to relieve this spasm too early, particularly if surgical intervention of the occluded artery is to be undertaken, may undo nature's protective mechanism and cause irreparable clotting.[1]

One of the most common causes of arterial occlusion is trauma in the form of lacerations or contusions. The laceration involving a vessel may be complete or incomplete, and the distinction between these two in the subsequent course is important. Where there is a complete laceration there are hemorrhage and spasm of the vessel involved. Where such a wound is seen early, a surgical repair of the severed artery is indicated and not technically difficult. The size of the lumen of an artery may be reduced by one half and still have 75 per cent of the normal blood flow through that vessel. Fine arterial silk sutures can be placed not involving the intima, and frequently a single running silk suture is all that is necessary (fig. 1). The hydrodynamic law that the wall pressure at any point is inversely proportional to the rate of flow aids us in this work. The rate of flow in a large artery is so rapid that the wall pressure is reduced. A portion of contiguous muscle can be sewed over the repair (fig. 2). Even veins may be similarly repaired and in the last six months I sutured two lacerations of the vena cava, accidentally produced during the removal of a kidney, satisfactorily with a single running suture. If the complete laceration is seen late, a resection of the artery and the accompanying vein is indicated. A large vessel should not be ligated in continuity. When the iliac artery must be divided a resection of the accompanying vein decreases the incidence of gangrene by approximately 12 per cent. This probably occurs by reducing the rate of venous return and permitting better peripheral nourishment by the restricted blood supply, entering the extremities through collateral circulation. When surgical repair has been attempted, heparin early and then dicumarol should be used, the bleeding time being maintained above fifteen minutes. Regardless of the type of operation, sympathetic nerve blocks should be repeated frequently. It is after the operation that the collateral circulation should be stimulated and spasm reduced or prevented. At times sympathectomy is indicated. The medical measures of stimulating collateral circulation by the abstinence of tobacco, the use of such vasodilatory drugs as whisky and papaverine, postural changes and externally controlled temperatures, and later exercises in a recumbent position are of great aid at this stage. Amputation is an indication of failure of previous surgical attempts and should be done only when all other efforts have failed. Ample time for demarcation and collateral circulation to develop should be given except in the presence of a spreading infection. When amputation is necessary, it should be of the modified guillotine type. By that is meant a simple amputation with the muscles cut slightly higher than the skin and the bone slightly higher than the muscles and the closure with loose approximation of the skin only, and retraction prevented by external traction. The making of flaps will result in pus pockets, gangrene and sometimes death, as has been proved so often in war surgery these last four years. Steel wire sutures reduce reaction.

The incomplete laceration of major vessels results in a hematoma, which may be of a pulsating type and with time develop into a so-called false aneurysm. Five such aneurysms were seen in transporting 450 wounded on one evacuation after the invasion of Pellelieu by a U. S. Navy hospital ship and it was necessary for me to operate on all 5 while at sea, 3 rupturing externally and 2 internally. If seen early, some of these lacerations may be repaired using again the fine arterial silk sutures. If this is not feasible, a resection of the artery and vein with subsequent nerve blocks should be done. After the aneurysm definitely has developed, one must determine whether it is arterial or arteriovenous.[2] Unless there have been serious hemorrhages or the tumor is rapidly enlarging, it is best to delay operation from three to six months to develop adequate collateral circulation. In the arterial type of aneurysm the obliterative opera-

[2] Pratt, G. H.: Surgical Treatment of Peripheral Aneurysm, Surg., Gynec. & Obst. **75:** 103-109, 1942.

tion is the one of choice; all collateral openings in the sac are sutured, and the sac itself is obliterated by the implant of a contiguous muscle. The retention of the sac is of primary importance,[2a] as the collateral vessels run in or near it; sac excision will interrupt these collateral vessels and cause a failure of the blood supply instantly. If the aneurysm is of the arteriovenous type, all vessels entering the sac itself should be resected and the sac removed (fig. 3). The collateral circulation in the arteriovenous type is so adequate that removal of the sac is not dangerous and its retention may result in a recurrence. Collateral vessels are so immature in the arteriovenous type that they tear frequently and hemorrhage is not unusual. An adequate supply of blood should be available at the time of operation. While in the Navy I operated on 18 aneurysms of traumatic origin, following these principles. Circulation was reestablished in all without the loss of any part of an extremity. In operations on 51 consecutive aneurysms there has been tissue loss in only 1 instance, and in that there was loss of one little toe.

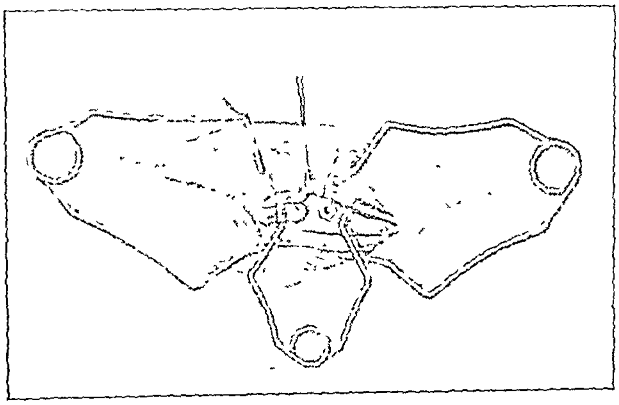

Fig. 1.—Arterial repair with fine surgical silk, not entering intima.

Contusions may cause local thrombosis, which if unrelieved may propagate and result in gangrene. If there are signs of arterial failure distally, the area should be explored and pressure removed. At times it may be necessary to open the artery and remove the thrombus. Frequently the resection of the vessel is necessary to prevent the thrombus from propagating.

Arterial embolism[3] causes the sudden occlusion of a major vessel, usually at a point of bifurcation. Thus we see them at the bifurcation of the aorta 12 per cent, at the division of the external and internal iliacs 18 per cent, at the femoral and the femoral profunda 50 per cent and at the anterior and posterior tibial arteries 12 per cent. Ninety-five per cent of these arterial embolisms develop from left sided heart disease of the rheumatic type with the addition of auricular fibrillation. There has usually been some exciting factor such as a surgical operation or the labor of pregnancy, which precipitates the embolism. The sudden pain, inability to use the part, coldness and a whiteness of the limb in the presence of auricular fibrillation are diagnostic. Surgical management by embolectomy is indicated if the patient is seen within twelve to twenty-four hours, and success depends on this time factor just as it does in ruptured peptic ulcer. Occasionally success may follow delay; I have removed an embolus successfully sixty hours after it occurred at the bifurcation of the aorta. Since most of these emboli occur in the lower extremities, the artery can be exposed just below the inguinal ligament where it is subcutaneously situated. A longitudinal incision in the artery is made and the site of the embolism determined by a probe. Ingenuity is sometimes necessary to remove the clot. Suction on a catheter, the formation of a corkscrew out of a silver or steel wire, forceps, and the manual milking with the hand have all been used successfully (fig. 4). After the clots are removed, the artery is washed with heparin solution and the wound closed by a single running silk suture, not entering the intima. Any generally trained surgeon is capable of performing this operation. Sympathetic nerve blocks after the operation and the use of heparin and dicumarol again are necessary. The medical measures to stimulate collateral circulation should be continued. Since the first successful embolectomy by Labey in 1911 there have been 382 recorded. I have performed the operation in 27 instances with a return of circulation at 61.5 per cent. Only 1 out of every 4 patients is alive today, death being due to the underlying heart condition, but this figure is favorably comparable to that of carcinoma of the breast after five years.

Arterial thrombosis may acutely occlude a previously diseased vessel. In these patients a large plaque may loosen from the wall and close the lumen like a trap door, or an artery gradually closing may suddenly close with a clot. It is rarely possible to remove such a thrombus because of the disease in the vessel. Sympathetic nerve blocks are at times helpful, but eventually amputation becomes necessary.

At times infection may cause acute occlusion, the streptococcus and the gas group of Clostridium perfringens being particular offenders. Their management includes the use of the sulfonamide drugs, penicillin and specific serums and, if uncontrolled, a relatively early amputation at the vital level, the level being determined by the color of the tissue, the fact that the muscle bleeds well and contracts when stimulated. While there can be no delay in amputation in the presence of the clinical picture of gas gangrene infection, it is well to add a word of caution at this time regarding the presence of air or crepitation in a wound. Crepitation does not necessarily mean a gas bacillus infection. The entry of a high velocity missile may drive air into the tissues, causing a crepitus, and the same may occur after puncture wounds from airplane or automobile accidents. The diagnosis of a gas bacillus infection should be made on the clinical picture with fever, a high pulse rate, sanguineous drainage from the wound, massive edema and the anxious sick look of the patient being suggestive. I received 6 patients aboard the U. S. Naval Hospital Ship *Relief*

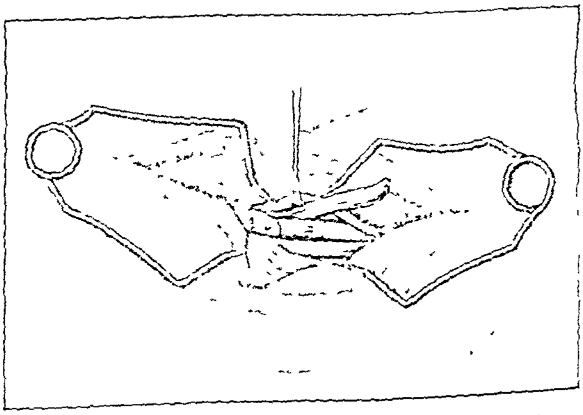

Fig. 2.—Repair of artery completed, reinforced with contiguous fascia.

for amputation on the basis of crepitation in the wound or Clostridium perfringens cultures. The clinical picture of gas gangrene was not present and in none of these 6 was amputation performed. These organisms are contaminants in many wounds and at times are controlled by penicillin. The mere presence of Clostridium perfringens organisms does not necessarily mean a gas bacillus infection unless the clinical picture also is present. Massive doses of penicillin may change our conception of gas infections.

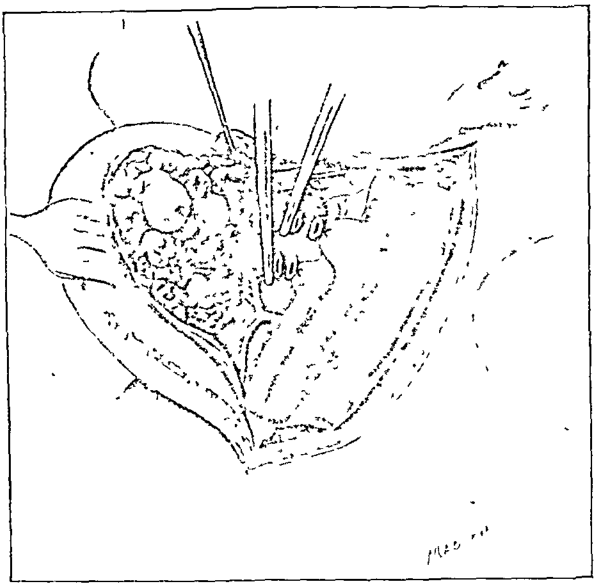

Fig. 3.—Arteriovenous aneurysm, showing the extreme degree of collateral development in the arteriovenous type. It was necessary to resect most of the carotid artery and jugular vein.

One of the most common causes for the occlusion of the artery of the upper extremity is a scaleneus anticus syndrome with or without cervical rib. This may cause a thrombosis of the subclavian artery with the symptoms of numbness, weakness, change of color, absence of the peripheral pulse and at times ulcers or even gangrene. When there is pressure on the brachial plexus, symptoms may be more neurologic. At such times the symptoms are of anesthesia and paresthesia with tingling and pain, particularly on the ulnar nerve side of the hand. Treatment for this condition is scalenotomy with removal of any bony obstruction (if present), the rib being rongeured away. A band to a rib from a long transverse vertebral process or an anomalous formation of the first or second ribs can produce a similar syndrome. After operation circulation should be stimulated through collateral circulation in the methods already mentioned, including stellate ganglion blocks or thoracic sympathectomy. The work of White and Smithwick has shown that the stellate ganglion should not be removed. Excising the stellate ganglion is a postganglionic operation and sensitizes the part to sympathin or epinephrine and produces greater spasm than before. A preganglionic operation can be done by dividing the sympathetic chain below the third dorsal ganglion, resecting the communicating fibers to the second and third intercostal nerves and a section of the nerves themselves and leaving the sympathetic chain and ganglions in situ. All connections between the chain and the costal nerves are interrupted. The retention of the chain and the stellate ganglion preserves the chain cells and prevents the postganglion sensitization type of reaction from occurring. White cleverly covers the sympathetic chain with a tantalum foil, and sews it into the intercostal muscle, further to insure no future connection with the nerves to the arm.

The recent war, partly fought in the arctic region, together with the submarine warfare and exposure of men to cold and wet in open boats, brought to prominence the lesions known as frostbite, immersion foot[4] and the so-called trench foot of World War I. The cooperation of the British and American medical services permitted these patients to be segregated and studied, and from this study a new conception of these lesions and their treatment evolved.

When a foot is frostbitten, actual freezing of the tissues occurs. In the immersion or trench foot syndrome the foot does not actually freeze, but it becomes chilled, anesthetic and edematous. In trench foot, trauma from walking or standing on these injured feet is added. At sea the feet are not traumatized, but, with the dependency in the water or in a boat, edema is severe and as the result of starvation and hypoproteinemia this edema is aggravated. Immersion foot may occur in prolonged submersion in warm water as well, the syndrome being a chemical edema one. The trench foot group are more prone to have infection and to lose the limbs. This was shown by the reports of White,[5] Patterson[6] and Anderson[7]—only 1 of 100 immersion feet was amputated, while 24 of 231 from Attu lost a foot or toes.

When the part is warmed and the circulation is restored to these limbs, it rapidly warms the deep tissues, and the contiguous transmission of this heat to the damaged skin surface causes discoloration and bleb formation. The circulation in the skin has been more impaired by the cold, particularly the venous and lymphatic vessels, and it is unable to remove the increased arterial supply rapidly, and blebs and edema result. If continued, the skin breaks and death of the superficial tissues occurs with gangrene. This excessive

vasodilatation of the part is probably due to the absorption of diseased tissue as the limb becomes warmer.

It was found early that patients themselves realized the danger of too rapid warming and return of circulation. Patients were seen to open windows and put their feet out and frequently complained that they were much more comfortable back in their life boats. This fact, and some judicious thinking by such men as Webster, Woolhouse and Johnson of the Royal Canadian Navy and White and Scoville[8] and others, led to the cooling or refrigeration treatment during this hyperemic stage. Therapy thus consists in cooling, best applied by temperature controlled cradles or ice bags and electric fans. In one to six weeks this stage has subsided and the superficial tissues can again carry the circulation load.

Many have residual pain and stiffness of joints and unhealthy thin skin. Biopsies have shown that there is a subcutaneous fibrosis which causes the inability of the tendons to flex well. Collagen deposits around the nerve cause the pain. Physical therapy, high vitamin diets and encouragement help at this stage. In those in whom burning pain persists when the peripheral circulation is impaired, or in the group in which spasm is a factor, lumbar sympathectomies are indicated. In these the response has been excellent. Nerve blocks should be done prior to this procedure to select the ones who will best respond. The residual causalgias are a sympathetic surgical problem. Our conception of therapy for these patients has changed often in the past years and no doubt will again. Only by pooling our knowledge and thoughts, however, can we progress. Perhaps the still unreported human experiments of the Germans, inhuman as they were, may help us when they are presented. Recently some work has been reported with the use of such anticoagulants as heparin to reduce the viscosity and coagulability of the blood, and this, in combination with refrigeration, offers the best possibilities at this time in the treatment of these patients. Dicumarol will also be of help in this respect. The hospital treatment, then, will consist in refrigeration of the part for a considerable length of time and the intravenous use of heparin. In controlled experiments only the limbs which were treated with heparin survived the refrigeration experimentally produced. Plasma will replace the lost protein. Prophylactically, much can be done for these patients. Certainly no one with a diseased artery should be exposed either in cold or wet weather or in refrigeration boxes or cars, and adequate covering against the weather and water without constriction of the part is important. It is well to remember that on even a moderately cold day the addition of a cold wind or wetting can produce this syndrome, and that repeated short exposures to extreme cold, such as running in and out of an ice box, may cause the same damage as a longer period of continuous cold of a low temperature. If one is wet and cold it would be well to remove any constricting type of gear, thus actually starting the treatment at that time. It is important that in the transportation to the hospital this chilling be continued. Again, anything which throws vessels into extreme spasms, such as tobacco, should be curtailed. Drugs such as alcohol, on the other hand, will be beneficial. Sympathectomy for residual pain or inadequate blood supply will remain the best delayed therapy for selected patients.

THE ORAL MANIFESTATIONS OF IRON DEFICIENCY

WILLIAM J. DARBY, M.D., Ph.D.
Nashville, Tenn

The recent recognition that lesions of the buccal tissues may be due to vitamin B complex deficiencies has led to the unjustified assumption by many that all such lesions are manifestations of vitamin deficiencies. In fact it has been claimed that changes in the lingual papillae are specifically due to niacin deficiency[1] and that the glossitis encountered in other conditions is probably due to "chronic niacin deficiency."[2] Similarly it has been implied that fissures at the angles of the mouth are pathognomonic of riboflavin deficiency[3] although it has been demonstrated that such lesions may heal following the administration of niacin,[4] pyridoxine[5] or pantothenic acid[6] or that they may be resistant to therapy with all known B factors.[7] Attention has been directed repeatedly to the multiplicity of etiologies of such oral lesions.[8]

The association of atrophy of the lingual papillae, glossitis and cheilosis with hypochromic anemia has been noted,[9] and the well known Plummer-Vinson syndrome[10] is characterized by stomatitis, dysphagia and hypochromic anemia. Vinson and Schmidt[11] have depicted the glossitis and perlèche which accompany this syndrome. The etiology of these oral changes is not clear. Vinson[12] has attributed the various evidences of malnutrition, such as anemia and glossitis, in these cases to interference with nutrition caused by the dysphagia. Kernan[13] reported examining a case resembling Plummer-Vinson's syndrome which exhibited atrophic lesions of various mucous membranes (nose, mouth, vagina, rectum) which were ascribed to a vitamin deficiency and suggested that esophageal scars and webs may form "on a basis of dietary deficiency." In a similar vein Wintrobe[14] writes that in chronic hypochromic anemia "The cheilosis of riboflavin defi-

ciency may be present." Meulengracht and Bichel[15] reported that riboflavin exerted beneficial effects on the external mouth lesions in cases of Plummer-Vinson syndrome but did not relieve the other manifestations including the dysphagia, a symptom which has been described as due to a deficiency of the vitamin B complex.[16]

Waldenström[17] in a too little known paper has presented clinical evidence interpreted to show that "fissures in the corners of the mouth, sores on the tongue, pains and spasm in the throat, changes in the nails and even vulvovaginitis may be healed after a sufficient administration of iron without any other therapy." Waldenström did not demonstrate that his cases were resistant to therapy with the B complex; hence his conclusions might be criticized on the grounds that the patients may have taken a better diet during the period of iron therapy and thereby overcome a concomitant B complex deficiency. The reported studies do not permit a decision as to whether such glossitis and cheilosis may be a manifestation of iron deficiency per se or whether their association with hypochromic anemia is due to an accompanying B complex deficiency. The absence of any general understanding of a possible role of iron deficiency in the production of these lesions of the oral mucosa is illustrated by the fact that Schour and Massler[18] in a recent review of the effects of dietary deficiencies on oral structures dismiss the subject with a single sentence: "The oral manifestations of iron deficiency have been given much less consideration than those of calcium deficiency and merit investigation."

It is my purpose in this report to present evidence that atrophic lingual papillae, glossitis and/or angular fissures which accompany iron deficiency anemias are often due to the lack of iron alone and not to accompanying B complex deficiencies. The frequent confusion of these cases with B complex deficiencies will be illustrated by the case reports. Finally, the effect of this finding on the interpretation of clinical evidences of the prevalence of B complex deficiencies within the general population as revealed by nutrition surveys will be discussed.

MATERIAL AND METHODS

The cases here reported were taken from the Nutrition Clinic of the Department of Medicine of Vanderbilt University Hospital with the exception of 1 (case 4), which I followed during a nutrition survey in North Carolina.[19] It has been a common experience in this clinic to encounter patients, especially women, with the recurrent oral signs as enumerated and with accompanying easy fatigability, indigestion, "nervousness" and other symptoms frequently ascribed to "subclinical B complex deficiency" but who fail to respond to therapy with adequate doses of pure or crude B vitamins. Many of these patients have dietary histories which appear adequate; that this is true has been substantiated by laboratory estimations on body fluids.[20] Such patients have been scrutinized in an effort to ascertain the origin of these lesions. From this group there emerged the study herein reported.

The iron absorption tests reported in some of these cases were carried out by the technic developed by Hahn and his co-workers,[21] utilizing radioactive iron. The absorption by an adult of more than 5 per cent of a test dose of radioactive iron is to be interpreted as definite evidence of the existence of an iron deficiency. Dr. Paul F. Hahn of the Department of Biochemistry of Vanderbilt University School of Medicine carried out these studies in 3 of the cases here reported.

The syrup referred to as B complex syrup contained 25 mg. of niacin, 1 mg. of riboflavin and 3 mg. of thiamine to 4 cc.

REPORT OF CASES

CASE 1.—Mrs. E. I. L., aged 38, white, quadrigravida, was first admitted on April 1, 1940 with the complaint of a hurting and burning of the stomach and chest after meals for the past five years. Her mouth had been constantly sore. There had been no diarrhea, but there had been constipation during the past three years. Increased tiredness had been noted. Examination revealed that the patient was apprehensive and underweight (weight 110 pounds [50 Kg.], height 63 inches [160 cm.]). The skin of the hands was hard and dry. There was oral sepsis, and the tongue exhibited imprints of the lower teeth without papillary atrophy. Moderate thyroid enlargement was noted, but there were no signs of toxicity and the basal metabolic rate was within normal limits. A diagnosis of "subclinical pellagra" and nodular, nontoxic goiter was made. She was treated by dietary instruction, plus brewers' yeast, cod liver oil and niacin 50 mg. three times a day. The teeth were extracted. Some improvement was exhibited, but she stopped coming to the clinic in October 1940.

The second admission of this patient was on Nov. 11, 1944, at which time she complained of pruritus vulvae of two years' duration. There were no other symptoms suggesting diabetes mellitus. The only other genitourinary complaint was frequent menses, occurring every two to four weeks. There were occasional hot flashes. Her tongue burned and her whole mouth was sore at intervals. She had worn dental plates for four years. One month previously she had had diarrhea for a fifteen day period.

On physical examination she appeared to be moderately well nourished (weight 123 pounds [56 Kg.]). There was dry pigmented skin of the ankles and shins, interpreted to be dermatitis ab igne. The lips were normal in appearance, the tongue was pink with definite atrophy of the marginal papillae. She wore dental plates. The right lobe of the thyroid was enlarged. An apical systolic murmur was heard on occasions. No alterations of reflexes were elicited.

Laboratory examination revealed a hemoglobin concentration of 10.5 Gm. per hundred cubic centimeters, an erythrocyte count of 3.90 million per cubic millimeter, a total white blood cell count of 7,300 per cubic millimeter, a packed cell volume of 36.5 per cent and a basal metabolic rate of —9 per cent.

She was treated with phenobarbital 0.03 Gm. three times a day and B complex syrup 4 cc. three times a day. On November 18 the patient was less nervous, but the sore mouth persisted. The epithelial tufts were absent from the filiform papillae, the tongue was slick along the margins and the tip, there were red denuded areas on the left margin and at the tip, and some central fissuring was present (fig. 1). The pruritus vulvae persisted. Treatment with B complex syrup was continued as before, and sodium perborate mouth wash was added. There was no improvement by December 6. The gynecologic consultant on that date reported no obvious cause for the pruritus. A negative thrush culture was obtained. The same therapeutic measures were continued until Jan. 10, 1945 with no improvement. The patient complained bitterly at this time of severe pruritus,

"rawness and burning of the tongue and lips" and of cracks in the corners of the mouth. The tongue continued to show the same abnormalities as before. The hemoglobin level was again reported as 10.5 Gm. Other laboratory findings of interest were a serum vitamin C of 0.3 mg. per hundred cubic centimeters, serum carotene of 347 micrograms per hundred cubic centimeters and serum vitamin A of 161 international units per hundred cubic centimeters.

A radioactive iron absorption test on Dec. 6, 1944 had revealed an uptake of 97 per cent of a test dose of 7 mg. On Jan. 10, 1945 there was prescribed 0.3 Gm. of ferrous sulfate three times a day in addition to the B complex syrup. One week later the patient volunteered the information "My mouth is well." The dusky spots had disappeared from the tongue, but the fissure and atrophic margin remained. By January 31 there had occurred further improvement on this regimen—the tongue and mouth were not sore, there was complete relief for the first time from the pruritus vulvae, and she was much less nervous. The tongue appeared to be normal on examination. The red blood cell count was 5.25 million, the hemoglobin was 12.5 Gm. and the packed cell volume was 44 per cent.

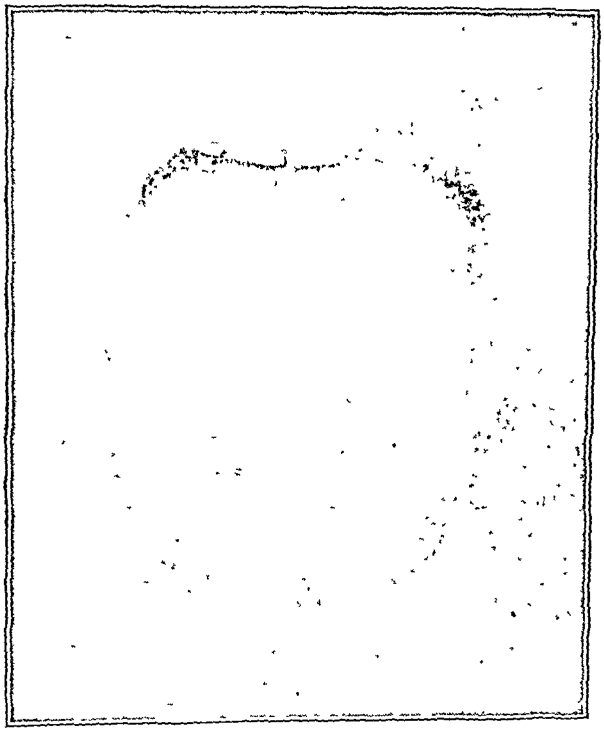

Fig. 1 (case 1).—Appearance on Nov. 18, 1944. Note the swelling of the tongue and the atrophy of the papillae. See text for complete description.

The administration of iron was continued, and on May 9 the hemoglobin had reached 13.0 Gm. and the packed cell volume 47 per cent. All therapy was discontinued on June 6, and the patient has continued well to date (five months).

This case presented the so-called classic symptomatology of "subclinical B complex deficiency"—a previous diagnosis of "subclinical pellagra," oral lesions, easy fatigability, constipation and a bout of diarrhea—yet she responded not at all to nine weeks of therapy with thiamine, niacin and riboflavin. She exhibited a mild hypochromic anemia, conditioned by excessive menstrual bleedings, and there was a very high iron uptake. It is certain that she was deficient in iron. One week of iron therapy was followed by subjective relief from the sore mouth, and within three weeks the appearance of the tongue was normal. This was accompanied by a satisfactory rise in the hemoglobin level and, interestingly enough, dramatic relief from a persistent pruritus vulvae.

Case 2.—Mrs. M. M., aged 31, white, a tertigravida, was first admitted on March 23, 1929 with the complaint of stomach trouble and shortness of breath. She had experienced a burning sensation in the epigastrium for many years. This had been treated by a Sippy regimen without success. While on the Sippy diet she had developed a dysphagia. A gastroenterostomy had been performed at another hospital, and the recovery was complicated by a generalized infection necessitating prolonged bed rest. Physical examination at this admission revealed that she was thin and nervous, was 65 inches (165 cm.) tall and weighed 99 pounds (45 Kg.). The mouth was edentulous, and the mucous membranes were pale. The tongue was coated except for some raw reddening over the anterior central portion. X-ray examination revealed the gastroenterostomy and spasticity of the colon. The red blood cell count varied from 3.5 to 4.3 million; the hemoglobin was from 60 to 88 per cent. No specific therapy was instituted, and the patient was discharged on the twenty-eighth day with the diagnosis of psychoneurosis.

The second admission was on April 18, 1937 with the complaint of a mass on the gums. The patient weighed 111 pounds (50 Kg.). The removal of a small fibroma from the gums was followed by considerable bleeding. The hemoglobin was recorded as 11.5 Gm. No other therapy was administered.

The third admission was on Feb. 9, 1943 for the complaint of bloating, smothering, shortness of breath, belching and dizziness. Since last seen in this clinic the patient had frequently experienced a sore mouth and tongue, and difficulty in swallowing. She had restricted herself to a diet composed largely of milk and free of meat because of the dysphagia. Her last menstrual period was in November 1942. On physical examination she was seen to be thin, pale and undernourished, and she weighed 106 pounds (48 Kg.). There was pitting edema of the ankles. She wore dental plates. There were scars at the corners of the mouth. The tongue appeared swollen and was denuded of papillae anteriorly. An apical systolic blow was heard. Laboratory findings of interest were an erythrocyte count of 3.32 million, hemoglobin of 4.7 Gm., packed cell volume of 24 per cent, a serum iron of 59 micrograms per hundred cubic centimeters and serum albumin of 4.8 Gm. per hundred cubic centimeters with a total serum protein of 6.6 Gm. per hundred cubic centimeters. The stool was negative for blood. The thiamine excretion in the urine, the serum carotene, vitamin A and ascorbic acid were all within a normal range. There was 20.5 degrees of free hydrochloric acid after histamine stimulation.

Treatment with ferrous sulfate, dilute hydrochloric acid and a regular diet was followed by a slow rise in hemoglobin and a small reticulocyte response (4 per cent). She was given a total of 1,500 cc. of blood by transfusion. The addition of brewers' yeast, cod liver oil and a high protein diet was made. On July 9 the red cell count was 4.46 million and the hemoglobin was 13.0 Gm.

On Aug. 3, 1943 the patient returned with the complaint of menorrhagia. Endometrial biopsy revealed an atrophic endometrium. Treatment with diethylstilbestrol was instituted, but she failed to return for complete follow-up.

On Sept. 24, 1944 the patient again returned because of menorrhagia. Ferrous sulfate, brewers' yeast and cod liver oil were prescribed, but the patient failed to take the iron because of a gastrointestinal disturbance which followed the first dose.

The patient was readmitted on April 14, 1945 with the complaint of nervousness and dysphagia. There had been no burning of the eyes, no paresthesias, sore mouth, skin lesions or diarrhea. The physical examination was essentially negative. The tongue had a "patchy coating with intact papillae." There were no neurologic changes. No edema was observed. Laboratory examination revealed an erythrocyte count of 4.08 million, hemoglobin 11.5 Gm. and white blood cell count 4,000. No therapy was instituted

On June 20 she complained of a sore mouth and tongue. Examination of the tongue revealed a patchy denudation of the epithelium (fig. 2). The hemoglobin concentration was 11.0 Gm. Radioactive iron absorption was 47 per cent of a test dose of 4 mg. Gastric analysis showed 10 degrees of free hydrochloric acid in the fasting specimen and 16 degrees in a specimen after alcohol. X-ray examination of the chest, gallbladder and gastrointestinal tract demonstrated no active lesions.

The oral administration of ferrous sulfate 0.3 Gm three times a day was instituted. The patient reported that the sore mouth disappeared within a week. On July 18 the dysphagia had also disappeared and the tongue was normal in appearance. The hemoglobin level had risen to 13.5 Gm and the packed cell volume to 43 per cent. On October 9 the patient continued to be free from complaints She weighed 106 pounds (48 Kg). The hemoglobin was 14.2 Gm, the red cell count 5.11 million and the packed cell volume 48 per cent. Iron administration was discontinued on this date. The tongue has remained normal (fig. 3).

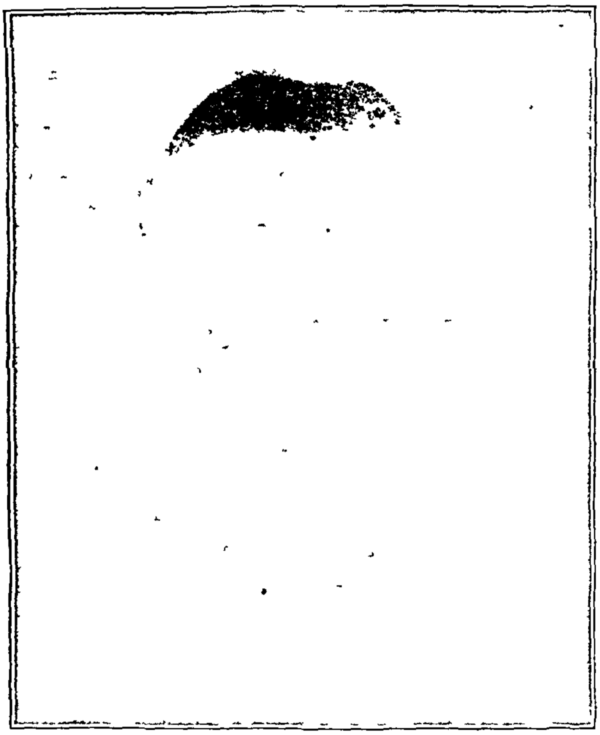

Fig 2 (case 2)—Appearance on June 20, 1945, showing the papillary atrophy and denudation of the epithelium before iron therapy was instituted

This history suggests a mild Plummer-Vinson syndrome. It is of considerable interest that the lesions of the tongue observed in this patient intermittently over a period of sixteen years were always accompanied by a hypochromic, iron deficiency anemia which can be attributed to abnormal blood losses. Again, the high iron absorption and the response to therapy proves the existence of the iron deficiency. The response of the tongue changes (compare figure 2 and figure 3) was purposely tested without preceding B vitamins in order to determine whether they responded to this single agent. It is not believed that the diet of the patient was altered during the last therapeutic trial, as no instructions were given her concerning diet and she did not gain in weight during the interval.

Case 3—Mrs. E. X, aged 36, white, a tertigravida, was admitted on Jan 25, 1932 with the complaint of weakness. All teeth had been extracted twelve years previously. Three years before she had undergone an abdominal operation, following which her menstrual periods had been of twelve days' duration. She weighed 111 pounds (50 Kg.) and was 65 inches (165 cm) tall Complete physical examination revealed nothing remarkable. Laboratory studies showed a red blood cell count of 4.0 million, with a hemoglobin concentration of 9.8 Gm. The impression recorded was psychoneurosis, adentia and secondary anemia She was treated with elixir of iron, quinine and strychnine, and psychotherapy, with some improvement.

The second admission was on Sept. 26, 1940, when the patient complained of choking with food for the past five years. During the last year the "least lump in food caused choking." She had noted intermittent cracking of the corners of her mouth for the past year. She had had a diarrhea the previous spring. There had been no dermatitis, no photophobia, no night blindness For the last few months the patient had experienced menstrual irregularities. Her dietary had included a quart of milk daily and liver once or twice a week. On physical examination she weighed 108 pounds (49 Kg.). Her lips were dry and shiny, there were fissures at the corners of the mouth, and a "splotchy reddening of the tongue with definite atrophy over the tip" was noted. The skin was dry, the nails pale. Slight ankle edema was present. Examination with the slit lamp revealed a slight but definite invasion of the cornea. Treatment with 4 mg. daily of riboflavin subcutaneously was instituted. On September 30 there appeared to be some improvement of the lip lesions, but the tongue was not altered. The hemoglobin at this time was 11.4 Gm, the erythrocyte count 3.94 million. The patient was advised as to a good diet, and supplements of dried brewers' yeast 30 Gm. three times a day were prescribed

On November 7 the patient weighed 114 pounds (52 Kg). The mouth was still sore despite the continuous administration of yeast. The dysphagia persisted. Therapy was unchanged. On December 5 the mouth was still sore and burning, and the angles of the lips were fissured. Her last menstrual period had been of two weeks' duration.

Despite the continued taking of the prescribed yeast and a dietary consisting of a quart of milk, ground meat or liver and vegetables each day, the sore tongue and weakness persisted until December 11. On this date the tongue showed an increase of the areas of redness, with definite papillary atrophy. The invasion of the cornea persisted. Treatment was instituted with 16 mg. of pyridoxine daily for a period of one week, with no improvement The yeast therapy was then resumed.

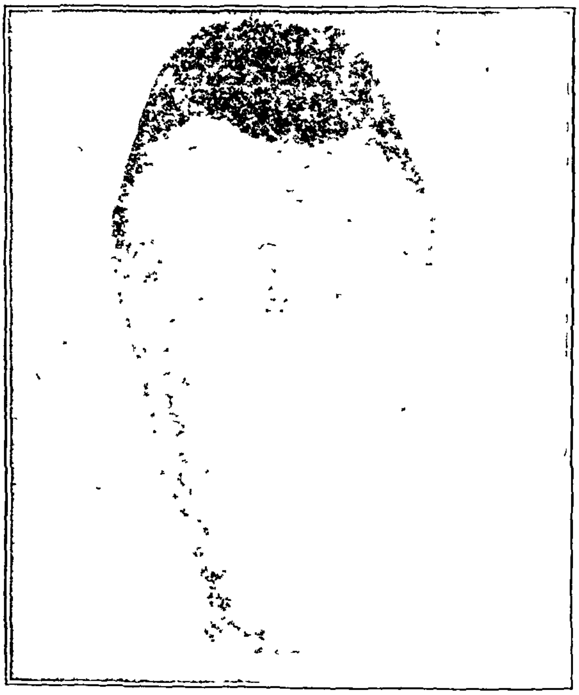

Fig 3 (case 2)—Appearance on July 18, 1945, showing the tongue following the administration of iron to the patient

On Jan 8, 1941 ferrous sulfate in doses of 0.3 Gm three times a day was prescribed On February 5 the patient had no sore tongue and the filiform papillae were numerous. The angular stomatitis had disappeared. The dysphagia was definitely lessened. The corneal invasion was still present on slit lamp examination. On March 5 the progress note recorded continuous and definite improvement since the moment iron was started. The iron therapy was continued, and on May 2 the hemoglobin level had reached 14.0 Gm. and the red cell count was 4.38 million. Gastric analysis showed no free hydrochloric acid after an alcohol test meal. The administration of ferrous sulfate was discontinued. The patient has been followed in numerous clinics through Oct. 9, 1945, with no return of the oral lesions or of the dysphagia.

This is again a case of Plummer-Vinson syndrome and illustrates the complete absence of any effect on the oral lesions or the dysphagia of the administration of B vitamins and the prompt and complete response to iron.

Case 4.—Mrs. R. D., aged 36, white, a quintigravida, who was seen on Sept. 9, 1943 during the course of a nutrition survey, had symptoms of a sore tongue and of fissures at the angles of the mouth for the past two months. About two months before she had noted a lower abdominal mass. On physical examination there were noted lesions at the angles of the mouth described as "honeycomb" crusts on a pink base. The tongue exhibited irregular atrophic areas. A lower abdominal mass, interpreted as a uterine fibroid, was palpated. Otherwise the routine physical examination was not remarkable. The cornea, examined with the slit lamp, showed definite capillary invasion. There was no photophobia. Laboratory examination revealed hemoglobin 9.3 Gm., erythrocytes 4.04 million, packed cell volume 30 per cent, plasma ascorbic acid 0.1 mg., plasma carotene 176 international units per hundred cubic centimeters, plasma vitamin A 69 international units per hundred cubic centimeters, total serum protein 6.7 Gm. per hundred cubic centimeters. The daily dietary intake calculated from a one week record included 0.91 mg. of thiamine, 1.07 mg. of riboflavin and 8.2 mg. of niacin and 1,650 calories.

Reexamination on October 11 revealed an identical condition of the eyes, tongue and lips. Treatment was instituted with ferrous sulfate 0.3 Gm. twice a day, plus riboflavin 5 mg. three times a day orally. On October 26 there was a definite subjective improved sense of well being, and the tongue and mouth were not sore. The oral lesions had completely healed. The corneal invasion persisted. The same therapy was continued. On November 11 the mouth and tongue were still normal, the corneal findings unaltered. The hemoglobin on this date was 13.0 Gm., the packed cell volume was 43 per cent and the red cell count was 4.92 million.

The findings in this case suggested a diagnosis of ariboflavinosis, but the failure of a response of the ocular lesions [22] and the reasonably satisfactory level of intake of riboflavin seem to contradict such a diagnosis. In view of the coexisting iron deficiency, the typical appearance of the lingual lesions and the response of the oral lesions alone, it now seems more reasonable to attribute these oral lesions to the lack of iron. At the time, however, it was thought that this response of the oral lesions was due to the riboflavin. This illustrates the confusion which may arise in the interpretation of the efficacy of a therapeutic agent unless the agents are tested separately, a point not always appreciated in published case reports.[23]

Case 5.—Mrs. M. L., aged 33, white, octigravida, was first admitted to the gynecologic service in October 1942 for a plastic repair of a cystocele and rectocele. There was no glossitis or cheilosis, and the hemoglobin concentration was 12.2 Gm. with a red cell count of 4.51 million. On April 29, 1943 the patient was referred to the medical service with the complaint of cracks in the corners of her mouth and occasional soreness of her tongue. During the previous month she had been given B complex syrup 4 cc. three times a day, with no improvement. The patient's dietary history and calculated dietary intake were reasonably adequate, with an average daily intake from food of 2.0 mg. of riboflavin, 1.5 mg. of thiamine and 8.66 mg. of niacin and 1,840 calories.

Physical examination revealed that the patient was underweight and worn (weight 87 pounds [39.5 Kg.] height 61 inches [155 cm.]). There were fissures at the angles of the mouth and atrophy of the papillae over the tip of the tongue. Slight photophobia was present, and on slit lamp examination there was grade 2 capillary invasion of the cornea. The laboratory findings of interest were hemoglobin 11.0 Gm., red blood cell count 4.10 million, packed cell volume 37 per cent. The serum carotene, vitamin A, ascorbic acid and serum proteins were within normal limits.

The patient was continued on the same dosage of B complex syrup with the additional administration of 5 mg. of riboflavin daily. No improvement had occurred in the oral signs or the corneal invasion by May 14. On the latter date pyridoxine 50 mg. three times a day was added to the other B vitamins which the patient was receiving. The mouth lesions seemed much improved by May 28, and the pyridoxine was discontinued. The oral lesions reappeared at intervals, however, and the supplementary B complex syrup was continued intermittently with or without the addition of brewers' yeast until Jan. 9, 1945. On this date the patient again had fissures at the corners of the mouth which did not respond to therapy with 12 Gm. of yeast three times a day.

On February 22 the patient returned complaining of the fissures at the angles of her mouth. The hemoglobin concentration was 11.0 Gm. Ferrous sulfate 0.3 Gm. three times a day was prescribed in addition to the yeast. On March 15 there was no soreness of the mouth. The packed cell volume had risen to 40 per cent. During the subsequent nine months there has been no recurrence of the angular fissures, and the tongue has remained normal in appearance. On April 30 the hemoglobin was 12.5 Gm., the packed cell volume 43 per cent and the erythrocyte count 4.40 million.

The recurring perlèche and atrophy of the tip of the tongue of this patient appeared after the development of a mild anemia of the iron deficiency type; it recurred despite therapy with B vitamins but has remained cured for nine months following the administration of iron. This treatment with iron resulted in a small but definite increase in the concentration of hemoglobin.

Case 6.—E. McN., a Negro woman aged 24, secundigravida, was receiving treatment for syphilis. During her last pregnancy (1941-1942) a single hemoglobin determination was recorded as 10.1 Gm. On Jan. 25, 1944 the patient presented herself with the complaint of lesions at the corners of the mouth for the past two weeks. Crusted, ulcerated lesions were present at the angles of the mouth. A history was given of excessive menstrual bleeding which necessitated bed rest during the past four menstrual periods. The hemoglobin concentration was 8.2 Gm., with an erythrocyte count of 3.80 million. Radioactive iron absorption studies showed an uptake of 34 per cent of a 15 mg. test dose. No therapy was instituted. On February 15 there had been a constant vaginal bleeding for two weeks. The hemoglobin was now 5.7 Gm. and the red cell count was 2.90 million. A second radioactive iron absorption showed a 55 per cent uptake of a 15 mg. dose. On February 24 treatment was instituted with ferrous sulfate 0.3 Gm. three times a day. The hemoglobin rose from 6.0 Gm. on this date to 10.0 Gm. on March 9. On the latter date the perioral lesions were almost healed. On April 13 the patient was completely asymptomatic. On July 25 her hemoglobin was 12.0 Gm. and red blood cell count was 5.0 million. She has experienced no recurrence of the oral lesions.

[23] Murphy, R. G., and Damarjian, E.: Riboflavin Deficiency with Idiopathic Hypochromic Anemia, Rhode Island M. J. **23:** 114 (July) 1940. Sevringhaus and Kybos.[2]

This woman represents an iron deficiency due to excessive blood loss and accompanied by the development of angular fissures. These fissures, as well as the anemia, responded promptly to therapy with iron alone.

COMMENT

The representative cases studied are interpreted as indicating that iron deficiency alone may be manifested by fissures at the labial commissures and a superficial glossitis. Such an interpretation is consistent with the experience of Suzman,[24] who reported 4 cases of Plummer-Vinson's syndrome with such oral lesions which healed rapidly following iron administration. It is of considerable interest that 1 of the cases which he described was treated for eleven days with liver extract No. 343, N. N. R., with no improvement in the oral lesions until iron was added. Furthermore, Waldenström [17] reported 4 cases of such oral lesions accompanying hypochromic anemia which responded to treatment with iron alone. He implied that an additional 4 patients in his series showed similar responses. All of these experiences confirm the conclusion of Waldenström [17] that these lesions of the mucosa and the dysphagia are both cured by sufficient administration of iron with no other therapy.

That these lesions are often confused with the oral signs of B complex deficiencies is evident from the therapeutic measures which were first instituted in most of the cases reported. The records of these individuals cover a sufficient period of time so that there is no doubt of the ineffectiveness of B vitamin preparations and of the efficacy of iron. No relapses during iron therapy have been observed in any of these subjects, in contrast to some of the reported cases of ariboflavinosis.[23] The therapeutic response to iron has been rapid (one to three weeks), again in contrast to the lesions of the tongue attributed to "chronic niacin deficiency." [26] The regeneration of the lingual papillae in iron deficiency has not been influenced by the administration of B complex vitamins.

It is of interest to point out that a number of the cases of glossitis or perlèche which have been reported as yielding slowly to vitamin therapy or of relapsing during or immediately following treatment [25] have been accompanied by anemias of the degrees seen in the cases here reported. Further, on occasions the use of combined iron and vitamin therapy has led to the disappearance of oral lesions, and the success has usually been attributed to the vitamins. Thus, Murphy and Damarjian [23] administered iron and riboflavin to a woman with anemia and cheilosis and ascribed the cure of the angular fissures to the vitamin therapy.

The appearance of the tongue in the cases reported has been somewhat characteristic. The descriptions all indicate a "blotchy, irregular denudation of the papillae," "absence of epithelial tufts" of the filiform papillae and often "dusky red irregular spots." None of these tongues have appeared scarlet like the glossitis of pellagra. It is of interest to compare the tongue depicted in figure 1 with that illustrated by Vinson and Schmidt [11] in a case of Plummer-Vinson syndrome. Both appear swollen with atrophic margins and "dusky spots." In case 1 there was no dysphagia. The bearing of these findings on the etiologic relationship of the oral lesions of the Plummer-Vinson syndrome is obvious. It is unnecessary to regard these signs as manifestations of a secondary vitamin deficiency, as has sometimes been done, but rather they are to be considered as part of the manifestations of iron want unless they fail to respond to adequate doses of iron. Furthermore, cases 1, 4, 5 and 6 reported here and case 11 of Waldenström [17] illustrate that the oral lesions may occur in absence of dysphagia.

It is not my intention to deny that a deficiency of riboflavin, niacin or other B complex factors may and sometimes does give rise to glossitis or cheilosis. Rather, it is emphasized that another cause of these signs is iron deficiency. Stomatitis due to the latter deficiency is now encountered much more frequently in the Vanderbilt Hospital Nutrition Clinic than is riboflavin or niacin deficiency cheilosis and glossitis.

This fact has prompted a study of the correlation of such oral signs occurring within the general adult population and the hemoglobin levels of the population. A composite of data to be published elsewhere tabulated from the results of three separate nutrition surveys [27] suggests that there is a much more frequent association of these signs with low hemoglobin levels than with high hemoglobin levels. Again, this illustrates the unreliability of a single clinical sign as the sole evidence for assessing the nutriture of a population.

SUMMARY

Six cases were observed which illustrate that angular fissures and superficial glossitis may accompany chronic iron deficiency anemia of mild degree. Certain of these cases responded to iron therapy alone; others responded to iron administration after they had failed to yield to prolonged intensive treatment with various B vitamin preparations.

Iron deficiency alone is a common cause of such oral lesions whether or not the lesions are accompanied by the dysphagia of the Plummer-Vinson syndrome.

Iron deficiency should be considered in the interpretation of the significance of such oral changes as are recorded in nutrition surveys.

The Value of Science.—That scientific knowledge can be applied to the material welfare of man is so obvious that no discussion of this value of science is necessary. Those who think that science has other values do not minimize its contributions to the feeding of human beings and their protection from the elements and from ill health. There are those, however, who deny that science has any value apart from these contributions to material welfare. Four grades may be distinguished in the scale of opinion: 1. Science has value only in serving the material wants of man. The only consideration is the material welfare of the community as a whole. This is the extreme totalitarian position. 2. Science has value in serving the material wants of man, but research workers do their best work if they enjoy it. 3. Science has value both in serving the material wants of man and also in enabling people to escape from certain mental evils. The study of science prevents unhappiness consequent on pettiness of outlook and produces forgetfulness of unpleasant memories. This rather negative position is that of Bertrand Russell. 4. Science has another value besides serving the material wants of man and enabling people to escape certain mental evils: it has a positive primary value as an end in itself, like music, art and literature.—Baker, John R.: Science and the Planned State, New York, Macmillan Company, 1945.

THE PROBLEM OF THE DANGEROUS CARRIER OF HEMOLYTIC STREPTOCOCCI

III. The Chemotherapeutic Control of Nasal Carriers

MORTON HAMBURGER Jr., M.D.
Chicago
and
CAPTAIN HENRY M. LEMON
Medical Corps, Army of the United States

The prevalence of epidemics of streptococcic[1] infection in the armed forces during World War II[2] has focused attention on the relation of "dangerous" carriers[3] of hemolytic streptococci to the spread of disease.[4] Exploration of this problem has shown that nasal carriers of these micro-organisms are more likely to transmit infection than throat carriers with negative nose cultures.[5] The reason for this is that the nasal carrier provides a much larger bacterial dosage for the infection of susceptible individuals than does the throat carrier, as demonstrated by quantitative cultures of the environment, including the air.[6] These facts apply equally well to hospitalized patients and to ambulatory carriers in army barracks.[7]

It was therefore important to know whether the nasal carrier state could be eliminated or modified by modern chemotherapeutic agents, for suppression of the dissemination of hemolytic streptococci by carriers would have many practical applications. Moreover, the suppressive action of sulfadiazine on streptococci in the nose would be of interest in an explanation of the mechanism of mass prophylaxis, which has heretofore been interpreted as due solely to the bacteriostatic effect of sulfadiazine in the mucous membranes of susceptible individuals.

The effect of sulfonamides and of penicillin on hemolytic streptococci in the nasopharynx has been described by various investigators,[8] but the significance of nasopharyngeal cultures in carriers is not the same as that of nose cultures.[6] Meads and his associates[9] have reported that penicillin injected at three to four hourly intervals eliminated the nasal carrier state in 3 patients with scarlet fever, though we are not familiar with similar reports dealing with sulfonamides. It is our purpose in this paper to describe our experience with the treatment of both hospitalized and ambulatory nasal carriers of group A streptococci at Fort Lewis, Washington, and Fort Douglas, Utah, with small doses of sulfadiazine or with calcium penicillin suspended in beeswax peanut oil. These preparations are suitable for use with ambulatory as well as hospitalized carriers.

METHODS AND MATERIAL

The following studies were made at the Madigan General Hospital, Fort Lewis, Washington, and in the Basic Training Section, Army Service Forces Training Center, Fort Lewis: Nose and throat cultures were made on soldiers admitted to the hospital with upper respiratory infection and those exhibiting cultures strongly positive for hemolytic streptococci selected for study. Some were treated as described later, while others served as untreated controls. There was no significant clinical difference between the two groups.

In the Basic Training Section nasal carriers of hemolytic streptococci were detected by periodic culture surveys of companies in training. In certain companies, arbitrarily selected, nasal carriers were treated as to be described and in other companies no carriers were treated. In both groups clinical and bacteriologic observations were continued as long as the men remained in their training units.

At Fort Douglas, Utah, sulfadiazine was administered to nasal carriers in an Army Student Training Program unit at the University of Utah in which an epidemic of streptococcic infection was taking place.

Types of Cultures Employed.—Four separate cultures for hemolytic streptococci were made in each hospitalized patient-carrier: (1) "noseblow cultures," (2) determination of the "streptococcus output," a measure of environmental contamination, (3) culture of nose swabs, (4) culture of throat swabs. Only the last two were performed on ambulatory carriers in barracks. A description of these methods follows.

"Noseblow" Cultures.—The number of streptococci expelled by blowing the nose was employed as a quantitative index of the effectiveness of treatment in the hospitalized nasal carriers and was determined in the following manner: The subject blew his nose into a sterile handkerchief and placed it in an Erlenmeyer flask containing 50 cc. of broth. After the flask was

Valuable technical assistance was rendered by Miss Valerie Hurst, Mrs. Margaret J. Green and Mrs. Ann Thompson.

From the Commission on Airborne Infections, Army Epidemiological Board, Preventive Medicine Service, Office of the Surgeon General, U. S. Army, and the Department of Medicine, University of Chicago.

Lieut. Robert M. Dalrymple, M. C., served as liaison officer for the commission at Fort Douglas, Utah, where some of these investigations were carried out. He contributed much of his time and energy and was solely responsible for the culture surveys made during the period of treatment of carriers at Fort Douglas.

The cooperation of the medical officers at Fort Lewis, Washington, and Fort Douglas made possible the studies herein reported. They were Col. Arthur R. Gaines, commanding officer, Madigan General Hospital, and his successors, Col. W. G. Jenkins and Col Maxwell Keeler; Lieut. Col. R. E. Tennant, executive officer; Col. Edgar Durbin, chief of the medical service; Major Harold Goler, chief of the respiratory disease service; Col. Luther R. Moore, surgeon, Ninth Service Command, Fort Douglas; Col. Irving S. Wright, medical consultant, Ninth Service Command, Lieut. Col. J. W. R. Norton, chief of preventive medicine, Ninth Service Command, Lieut. Col. W. G. Mitchell, commanding officer, Station Hospital, Fort Douglas, Major Lloyd W. Robinson, chief of the medical service, and Lieut. Irving Imber, chief of the labor service

shaken for thirty seconds an aliquot was removed for making a blood agar pour plate, which was incubated overnight. The colonies of beta hemolytic streptococci were counted.[10]

"Streptococcus Output."—The "noseblow" culture represented the carrier's potential ability to contaminate his environment.[11] The actual environmental contamination was estimated by a method previously described[6] and consists in pinning or stapling a 5 inch square cotton patch to the bottom sheet of the carrier's bed at the level of the chest and leaving it in place overnight. The next morning the patch is removed and cultured as described under "Noseblow Cultures."

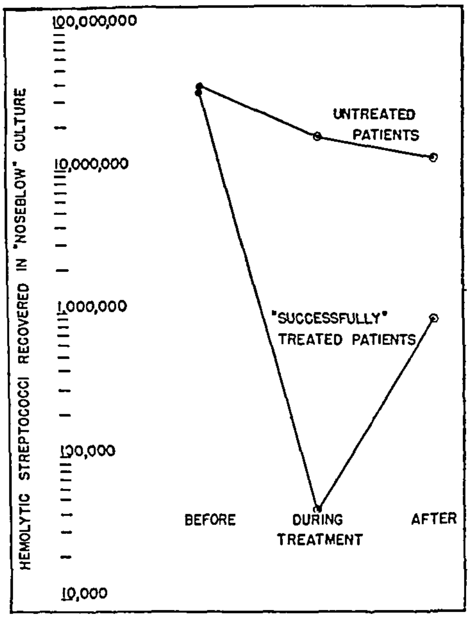

Chart 1—Effect of 1 Gm of sulfadiazine per day on the number of hemolytic streptococci recovered in "noseblow" cultures of hospitalized patient carriers. Treatment was continued for from five to ten days, in most cases six days. In order to compare time periods as fairly as possible, the first to fifth hospital days of untreated patients are plotted on the same ordinate as "before treatment," the sixth to tenth as "during treatment" and the eleventh to fifteenth as "after treatment" Technic of noseblow culture is described in text The curves represent the average of 23 untreated and 22 "successfully" treated patients Note logarithmic scale.

Throat Culture.—A sterile swab was rubbed over the tonsils or tonsillar area and sometimes over the posterior pharynx as well. It was then inoculated directly on to a horse blood agar plate containing 0.1 per cent of para-aminobenzoic acid and the colonies spread with a loop. The plate was incubated for eighteen to twenty hours.

The method of reading plates, described elsewhere in detail,[12] estimates the number of colonies of beta hemolytic streptococci as strongly positive (++++), moderately positive (++) or weakly positive (+).

Nose Culture.—A cotton applicator was inserted gently into the nostril for a distance of 3 to 4 centimeters, rubbed against the mucous membranes and inoculated on to a quadrant or half of a horse blood agar plate. It was not necessary to spread the colonies with a loop. Incubation and reading of plates were the same as for throat cultures. Additional details of the technic have been described elsewhere.[6]

Identification of Beta Hemolytic Streptococci.—Beta hemolytic streptococci recovered before treatment, and when present during and after treatment, were grouped and typed by the method of Swift, Wilson and Lancefield.[13]

Sulfonamide Blood Levels.—The level of free sulfadiazine was determined almost daily in hospitalized carriers and semiweekly in ambulatory carriers. The method of Peters,[14] utilizing capillary blood, was found quite satisfactory for this purpose, when modified to permit the use of only 0.1 cc. of blood. The results obtained by this method correspond closely with those obtained by that of Bratton and Marshall.[15] A photoelectric colorimeter with a suitable filter was used to increase the sensitivity of the para-dimethyl-aminobenzaldehyde color reagent.

RESULTS

Effect of 1 Gm. of Sulfadiazine a Day on the Dispersal of Streptococci by Hospitalized Patient-Carriers.—Twenty-six patients with strongly positive nose cultures for group A streptococci were given 1 Gm. of sulfadiazine a day for five to ten days. The effectiveness of the drug was assessed by daily or nearly daily quantitative noseblow cultures, determination of the "streptococcus output" and nose and throat cultures.

Charts 1 and 2 demonstrate the reduction by sulfadiazine in the number of streptococci expelled by blowing the nose, and in the degree of environmental contamination as indicated by the "streptococcus output," in 22 of the 26 subjects. Moreover, the nose culture (swab) became negative in most but not all these patients in two to five days. It should be pointed out that the bacteriostatic effect was usually not

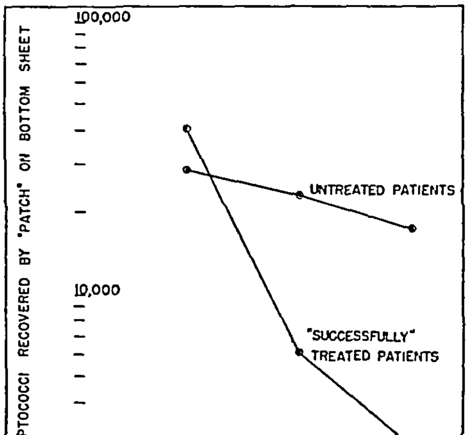

Chart 2—Effect of 1 Gm. of sulfadiazine per day on the environmental contamination produced by patient carriers with strongly positive nose cultures See explanation of chart 1.

---

[10] The importance of streptococci expelled by blowing the nose will be discussed in another communication[11]

observed until about forty-eight and occasionally seventy-two hours after the first dose. Of the 4 unsuccessfully treated carriers, 2 harbored sulfonamide resistant type 17 streptococci before treatment was started,[16] 1 did not achieve adequate blood levels and the fourth suffered from bilateral maxillary sinusitis.

Two additional points of interest were, first, that the streptococci returned to the nose, usually in relatively small numbers, after the cessation of therapy in 95 per cent of the patients and, second, that the throat culture often remained positive even though the nose culture and noseblow were rendered negative. Typical protocols are presented in table 1.

Treatment of Ambulatory Nasal Carriers with 1 Gm. of Sulfadiazine per Day.—The assessment of therapy of ambulatory carriers is less satisfactory than that of hospitalized carriers because they are more difficult to control and because observations cannot be made as frequently as in hospitalized persons. The present series includes only men whose noses were swabbed sufficiently often to permit an evaluation of their cultures five days after the first strongly positive nose culture.

Experience in treating nasal carriers where streptococcic disease was epidemic was provided by an outbreak in the spring of 1945 in an Army Student Training Program unit whose personnel was hospitalized at Fort Douglas, Utah. The carriers received 1 Gm. a day for thirty-two days. Here the effectiveness of treatment appeared to be directly related to susceptibility of the organisms to sulfonamide, for 90 per cent of 29 sulfonamide sensitive type 19 strains responded quickly, whereas 83 per cent of 6 sulfonamide resistant type 17 strains failed to respond.[17] The contrast between these type 17 and 19 cultures is illustrated in charts 3 and 4. Not only did the type 17 strains resist the action of sulfadiazine in the carriers, but they actually infected several other individuals, including

TABLE 2.—*Sulfadiazine Treatment of Ambulatory Nasal Carriers of Hemolytic Streptococci at Fort Lewis and Fort Douglas*

	Per Cent of Carriers Whose Nose Cultures Were Negative or + 5 Days After Initial +++ Culture	Average Duration of Treatment, Days	Number of Carriers
Fort Douglas carriers, streptococcus type 19, sulfonamide sensitive	90	32	29
Fort Douglas carriers, streptococcus type 17, sulfonamide resistant	17	32	6
Fort Lewis carriers, streptococcus types 1, 3, 6, 11, 12, 14, 17, 19, sulfonamide sensitive	68	23	19
Fort Lewis carriers, untreated	34	0	29

The sulfonamide sensitivity refers to tests of strains recovered prior to treatment.

[16] Another carrier of sulfonamide resistant (before treatment) type 17 streptococci, who produced as great environmental contamination as we have ever observed, was treated with 6 Gm. of sulfadiazine per day (table 1). He continued to disperse great numbers of type 17 streptococci and infected four nearby patients with this organism.

[17] The sulfonamide sensitivity of these strains was tested in vitro by the method of A. T. Wilson (Method for Testing in Vitro Resistance of Group A Hemolytic Streptococci to Sulfonamides, Proc. Soc. Exper. Biol. & Med. 58: 130-133, 1945), and in tryptose phosphate broth enriched with horse serum. These studies will be reported elsewhere.

successfully treated carriers of type 19 who were still receiving the drug.

At Fort Lewis, where streptococcic disease was not epidemic, carriers were detected by periodic surveys.

Table 5.—*Levels of Penicillin in Blood Serum Following a Single Intramuscular Injection of 300,000 Units in Beeswax Peanut Oil: Reports of Various Investigators*

Investigators	Oxford Units Per Cc. of Serum at Different Times After Injection of Penicillin: 12 Hours	24 Hours	Number of Cases
Nichols and Hounz[22]	0.18	0.03	8
Romansky and Rittman[21]	0.039-0.625	0.000-0.625	87
Kirby and others[20]	0-0.2	0	54

Sixty-eight per cent of 19 treated carriers exhibited negative or very weakly positive nose cultures by the end of five days, as contrasted with 34 per cent of 29 untreated carriers who underwent spontaneous remissions during that time. The data on the ambulatory carriers are summarized in table 2.

Nose Culture Relapses in Sulfadiazine Treated Carriers.—When treament was discontinued after five to ten days, as was done with the hospitalized patient-carriers, the relapse rate was very high, 95 per cent, as contrasted with 23 per cent in the ambulatory carriers treated for an average of twenty-three days. These data are summarized in table 3.

Much of this difference may be due to the duration of treatment, since a similarly high relapse rate was seen in several ambulatory nasal carriers in whom treatment terminated after a few days.

Follow-up data after the cessation of treatment were not available on the Fort Douglas men.

Sulfadiazine Blood Levels.—Levels were determined on hospitalized men every one to three days and on ambulatory carriers once or twice a week. The average levels are presented in table 4.

Toxic Reactions to Sulfadiazine.—Untoward reactions were uncommon. The only objective reaction was the appearance of a morbilliform rash in 3 of the ambulatory carriers at Fort Lewis and Fort Douglas. Two men complained of feeling tired while taking the drug.

* Nose blow cultures are expressed as the average of several cultures made in the before, during and after treatment periods.
† The streptococcus output is the number of streptococci recovered by the highest of several patches cultured in the before, during and after periods.

The Effect of Calcium Penicillin in Beeswax Peanut Oil.—Though the action of penicillin on hemolytic streptococci is very rapid, the necessity of injections every three to four hours has rendered its use impracticable in the treatment of ambulatory carriers; but the recent development of a suspension which is so slowly absorbed from the tissues [18] that only one injection a day may be necessary suggested a trial of this material. Accordingly, two lots of calcium penicillin suspended in 4.8 per cent beeswax by weight in peanut oil were sent us by Capt. Monroe J. Romansky of the Army Medical School. Each cubic centimeter contained 300,000 units of penicillin.

Though the treatment of both ambulatory and hospitalized carriers is the ultimate goal in the use of this material, the clinical trials were conducted on hospitalized carriers because daily careful observation was deemed important. The 14 subjects were divided into two groups: 7 patients still acutely ill and 7 ambulatory patients detained past the time when the ward officer would have discharged them. The latter served as true examples of postinfection healthy carriers. Though the number of cases in the series is small, they illustrate the advantages and shortcomings of this preparation.

One cc. was injected daily into the deep muscles of the upper outer quadrant of the buttock on alternate sides each day. Ten men received five daily injections, 2 men six and 2 men seven. Twelve of the 14 subjects experienced but slight discomfort in the buttock and stated that they believed they could perform full duty while under treatment. One of the other two experienced severe pain along the leg for several hours, and one man complained of severe pain and tenderness at the site of injection lasting nearly twenty-four hours.

The bacteriologic study followed the plan of the patients treated with sulfadiazine, and the findings are summarized in table 5. The immediate results were dramatic. In every case the streptococci in the "noseblow" culture [19] were either eliminated or diminished by more than 98 per cent after the first injection of penicillin. The nose and throat swab cultures and the "streptococcus output" followed the same pattern.

---

[18] Romansky, M. J., and Rittman, G. E.: A Method of Prolonging the Action of Penicillin, Science **100:** 196-198, 1944.

[19] Penicillinase 2,500 units, supplied by Captain Romansky and Dr. A. J. Liebmann of the Schenley Laboratories, was added to the flask containing the "noseblow" material to inactivate any penicillin which might have been carried over in the nasal secretion. The flask was incubated at 37 C. for fifteen minutes before an aliquot was removed for making a pour plate.

Blood levels were not measured, though the bacteriologic results suggest that absorption may have been irregular in some cases. The levels encountered by other investigators using this preparation have varied considerably, however, and are summarized in table 6. The most striking difference between two large well studied series was the finding in one [20] that no penicillin could be demonstrated in the blood serum twenty-four hours after the intramuscular injection of 1 cc. of 300,000 units of calcium penicillin in beeswax peanut oil, whereas bactericidal concentrations were detected in most patients in the other series.[21] Bactericidal concentrations were demonstrated at the end of twenty-four hours in a third small group of cases,[22] but the method employed for measuring blood levels differed from that used in the two larger series.

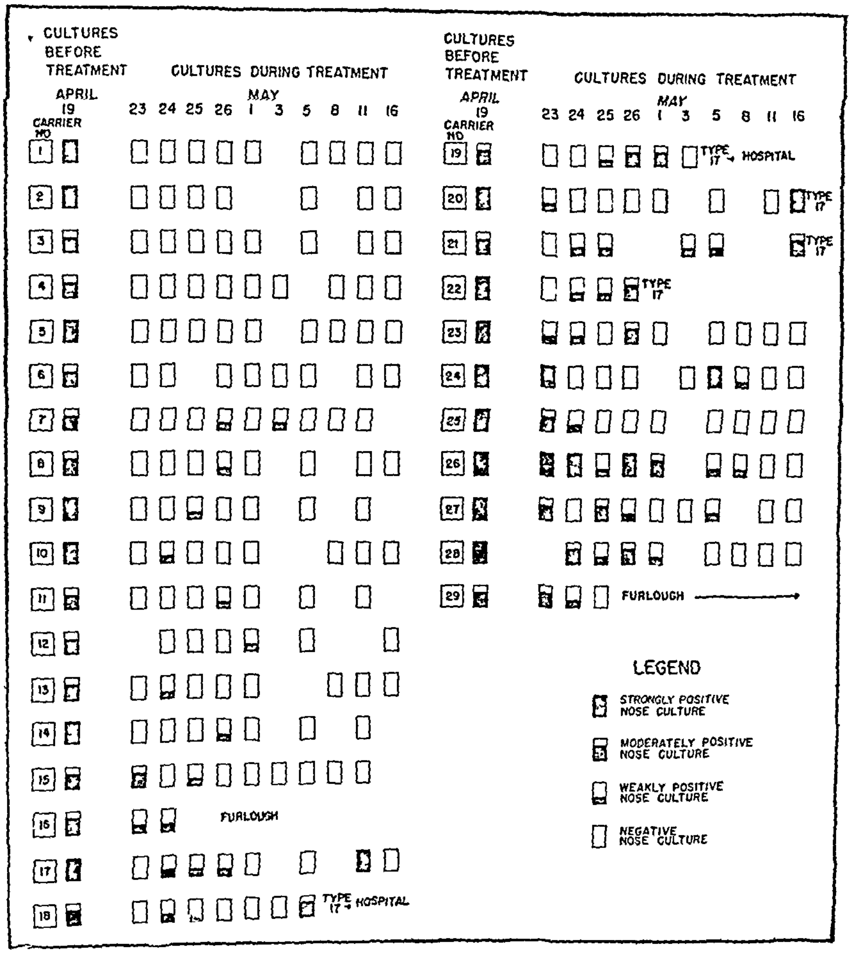

Chart 3.—Effect of 1 Gm. of sulfadiazine per day on the nose culture of ambulatory carriers of type 19 streptococci. These strains were susceptible to sulfadiazine in vitro Note that several carriers became infected with sulfonamide resistant type 17 streptococci while they were still receiving sulfadiazine.

Relapses Following Penicillin.—In 7 of the 14 carriers the noseblow, nose culture, throat culture and streptococcus output remained entirely negative for follow-up periods of eleven to seventy-two days after the last injection. In other words, the carrier state was effectively and probably permanently eradicated. One carrier suffered a relapse of his throat culture seventeen days after the cessation of treatment, but his nose remained free from streptococci.

Relapses of nose culture, noseblow and throat culture occurred in the remaining 6 carriers within one to five days after the last injection of penicillin, though only 2 dispersed many streptococci into the environment. It was of course important to analyze as far as possible the reasons for these relapses. Because of the equal distribution of certain factors among the carriers who did and who did not relapse, these factors could be ruled out as at least constant sources of failure. They were (1) streptococcus type, (2) presence or absence of sinusitis, (3) total dose of penicillin, 2 men receiving 2,100,000 and 1,800,000 units being among the failures, (4) duration of positive culture before treatment, (5) presence of tonsils and (6) sensitivity of the streptococci to penicillin.[23] Unfortunately, the absence of penicillin blood levels renders it impossible to say whether absorption was always adequate.

COMMENT

The primary aim in the treatment of carriers of any pathogenic microorganism is the complete eradication of the carrier state. When this cannot be accomplished, as is often the case, the next goal is to render the carrier as harmless as possible.

The prompt and lasting elimination of all hemolytic streptococci from the nose and throat of a carrier can be effected in many cases by penicillin in beeswax peanut oil injected once a day for five to seven days. Moreover, the majority of those carriers who relapsed after termination of treatment failed to disperse large numbers of streptococci into the environment. Therefore a method is now available for controlling well over half the dangerous carriers in event of an epidemic. Furthermore, if the cause of relapse in certain cases in the present series was inadequate absorption of penicillin, as suggested by the studies of Kirby and his associates,[20] an increase in dosage may offer hope of a substantial augmentation of the number of individuals in whom the carrier state is completely eradicated. Their data suggest also that subcutaneous administration of 300,000 units in beeswax peanut oil may provide adequate blood levels. However, since the levels achieved by this group after intramuscular injection are considerably lower than those reported by Romansky and Rittman [21] the problem obviously needs further investigation. Finally, the prompt suppression of the carrier state, associated with considerable reduction in the dispersal of streptococci into the environment of every treated carrier, is significant, even though relapses often occur.

[22] Nichols, D. R., and Haunz, E. A.: Prolonged Action of Penicillin in Mixtures of Beeswax and Peanut Oil, Proc. Staff Meet., Mayo Clin. **20:** 403-407 (Oct. 31) 1945.

[23] The in vitro sensitivity to penicillin of strains recovered from 3 patients after relapse and of two strains recovered before treatment from patients who did not suffer relapse was tested by Mrs. Lida H. Mattman by a simple unpublished method developed in the laboratory of the Harrison Department of Surgical Research, University of Pennsylvania School of Medicine. The penicillin sensitivity of all of these five strains was the same.

In view of the efficacy of penicillin and the appearance of epidemics of sulfadiazine resistant streptococcic disease following mass sulfonamide prophylaxis,[24] the circumstances under which sulfonamide treatment of nasal carriers may be advisable must await further experience. It is possible that, in small groups where penicillin may not be available, nasal carriers of sulfonamide susceptible hemolytic streptococci may be profitably given sulfadiazine for three to four weeks. This can apparently be done without danger of sensitizing the patient.[25]

The role played by sulfadiazine given as mass prophylaxis in preventing the dissemination of hemolytic streptococci from nasal carriers is of interest in considering the mechanism of the initial success of the programs carried out by the Navy and the Air Forces in 1944.[26] Though it has been well recognized that sulfonamide drugs fail to eliminate streptococci from the throats of most carriers,[8] there has heretofore been no information concerning their effect on the dispersal of streptococci from the upper respiratory tract. The results reported in this paper suggest that sulfadiazine, in addition to creating in susceptible hosts an environment unfavorable to the implantation of sulfonamide sensitive streptococci, also hinders their dissemination by dangerous carriers. Moreover, the failure of sulfadiazine to reduce environmental contamination resulting from carriers of sulfonamide resistant strains could explain the ultimate replacement of sensitive by resistant strains in the treated population.

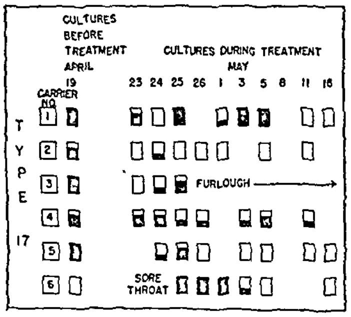

Chart 4.—Lack of effect of 1 Gm. of sulfadiazine per day on the nose culture of ambulatory carriers of type 17 streptococci. All these strains were resistant to sulfadiazine in vitro. See legend of chart 3.

SUMMARY

1. The effect of sulfadiazine and of slowly absorbed penicillin on group A hemolytic streptococci in the nose of carriers and on their dispersal into the environment has been investigated.

2. One Gm. of sulfadiazine a day eliminated or reduced the numbers of sulfonamide sensitive streptococci in the nose and inhibited the dispersal of these organisms into the environment in about 80 per cent of cases. It was ineffective against sulfonamide resistant streptococci.

Streptococci of the same serologic type reappeared in the nose after the cessation of treatment in 95 per cent of carriers treated for five to ten days but in only 23 per cent of carriers treated for an average of twenty-three days.

3. The inhibitory effect of "prophylactic doses" of sulfadiazine on the dispersal of sulfonamide susceptible streptococci by carriers suggests that a direct effect on the carrier state probably played an important role in the initial success of the mass prophylaxis of streptococcic disease carried out by the Navy and Air Forces in 1944.

4. Calcium penicillin in beeswax peanut oil was administered to 14 carriers in a dosage of 300,000 units in 1 cc. a day intramuscularly for five to seven days. Prompt and permanent eradication of both nose and throat carrier state and of the dispersal of hemolytic streptococci occurred in 50 per cent of these carriers. In the other 50 per cent streptococci were eliminated or reduced by more than 98 per cent in number during the administration of the penicillin, though relapse took place after it was terminated. Most of the carriers in whom relapse occurred dispersed very few streptococci into their environment.

5. Calcium penicillin in beeswax peanut oil can be administered to most ambulatory carriers in daily 1 cc. doses intramuscularly without interference with their normal activities.

NONOPERATIVE TREATMENT OF OSTEOMYELITIS WITH PENICILLIN

EDWIN J. GRACE, M.D.
Brooklyn
and
VERNON BRYSON, Ph.D.
New York

In a preliminary report[1] the advantages of treating chronic osteomyelitis with penicillin and a wetting agent (sodium tetradecyl sulfate) were presented. Seven of the most severe cases that have been observed since publication of our earlier report will now be reviewed by way of confirmatory evidence on the soundness of the procedure.

At the present time, results obtained by nonoperative treatment of chronic osteomyelitis appear to justify further comment on this simple therapeutic program, particularly since three of our large military hospitals have recently reported a series of cases in which the topical principle of therapy has been neglected in favor of more radical methods.

Never in all history have we been confronted with mutilation of the magnitude now seen, not only here but throughout the world. An enormous number of these tragic casualties are suffering from chronic osteomyelitis and face a hopeless future of invalidism. To date all known methods of surgical treatment have often been inadequate and amputation must be performed in some cases. Confronted by this fact, it is imperative that the surgeon reexamine the status of accepted practices used in treating the disease.

The medical profession is at present represented by two opposing points of view concerning the basic course to be followed in dealing with the patient with chronic osteomyelitis: One group may be described as the exponent of radical surgery and represents the majority trend in military medicine. Essentially the method advocated consists in extensive saucerization of the affected region, with an attempt to remove mechanically

[1] Grace, E. J., and Bryson, Vernon, Topical Use of Concentrated Penicillin in Surface-Active Solution, Arch. Surg. **50:** 219 (April) 1945.

all possible infective foci. Skin grafting may be employed and becomes almost a necessity when the excision of bone and muscle has resulted in a wide area of exposure.[2] The resultant cosmetic effect, even when there is no impairment of function, should hardly receive the unqualified endorsement of individuals on whom such operations are performed. Yet to the surgeon the arrest of osteomyelitis may be regarded as evidence of success, regardless of prolonged hospitalization and possible mutilation attendant on the method.

According to another point of view, as held by us and a minority of others, primary reliance in treating chronic osteomyelitis should be placed on chemotherapy, with surgical intervention reduced to a minimum compatible with successful treatment. The word of Anderson and his associates[3] supports the contention that a favorable outcome may usually be anticipated when a program of penicillin therapy is combined with conservative surgery. Our own studies with penicillin-detergent combinations are designed to eliminate, by means of the detergent, the isolation of penicillin-susceptible bacteria in sequestrums, sclerosed bone, abscesses, poorly vascularized sinus tracts and soft tissue scars. It then becomes possible to eliminate concurrently the bacteria themselves, utilizing the antibacterial properties of penicillin as enhanced by the presence of the detergent. Experiments now in progress show that the familiar stimulation of the bacterial properties of antiseptics in the presence of detergents[4] is also noted in combinations of penicillin with the wetting agents that we have used. A report of this work will be published elsewhere.

No complete judgment of the efficacy of penicillin-detergent combinations can be made until time has elapsed and the percentage of recurrent infections is tabulated. Yet one must remember that surgery alone is too often merely palliative and the spectacle of a patient with a history of from forty to fifty operations is not unusual. Therefore it would seem that the use of chemotherapy, a conservative and nonmutilating treatment, should be made the method of first choice in treating our war wounded, even though in some cases it may not prove to be ultimately successful. Where failures or relapses occur there is still time enough for the prolonged hospitalization and possible disfigurement attendant on saucerization and the inevitable removal of some healthy tissue. In the meantime our limited experience suggests that the employment of penicillin with a wetting agent is well suited for the nonoperative treatment of chronic osteomyelitis and deserves wider attention when considered in conjunction with the inadequacies of accepted surgical practice.

THERAPEUTIC PROGRAM IN CASE REPORTS

Unless noted, the plan of therapy in all of these cases has been essentially the same: First, a complete physical examination with correction of obvious deficiencies such as anemia and focal infection. The latter we feel is vital and no therapy is undertaken until all dental sepsis, such as devitalized teeth or apical infection, has been removed; all cavities must likewise be filled. Tonsils are removed in every case in which they appear infected clinically or if this is advised by the otolaryngologist. In the male, infection of the prostate is often a factor, and in some of our more advanced cases of osteomyelitis we have encountered previously unrecognized cases of prostatic infection.

After these preliminary steps have been carried out the patient is hospitalized for ten days and during this period he receives penicillin as follows: Injections of approximately 3 cc. (more or less depending on the size of the sinus) of a solution made up of 200,000 units of penicillin dissolved in 25 cc. of a wetting agent (Aerosol O. T. or sodium tetradecyl sulfate 0.1 per cent) into each sinus every three hours. Appropriate needles must be used to follow the sinus tract to the infected area of bone and an effort must be made to flood the solution into the diseased area. This is supplemented by intramuscular injections of 20,000 units every three hours for the first four doses and then 10,000 units every three hours. The medication is continued regularly night and day throughout the period of hospitalization.

In some cases now under treatment we have increased the topical application to 20,000 units per cubic centimeter or 1 million units per 50 cc. We do not allow more than 25 or 50 cc. of the penicillin and wetting agent to be prepared at a time in order to insure a fresh solution and prevent deterioration of the penicillin.

REPORT OF CASES

In an earlier publication[1] we reported a case in which chronic osteomyelitis with a chronic purulent discharge had been present for nine years. The discharge has not reappeared since treatment with penicillin and the detergent. This now represents an eleven month follow-up.

Case 1.—A man aged 39, a delivery man, first seen at the Grace Clinic on July 24, 1945, presented the complaint of chronic osteomyelitis. In 1921 he had been injured in a basketball game and had developed osteomyelitis of the left tibia. After one year this cleared up and remained so until 1938, when he had a recurrence which lasted for five months. It broke down again in 1941 and he was ill for three months. Since this time he has had recurrent breakdowns of the wound at intervals of about three months. He has had seven surgical procedures performed on this leg to date. There have been no other complaints.

The skin over the left tibia was red and inflamed, with dense scar tissue from previous surgical operations. There was a sinus at the upper end of the left lower leg extending to the bone. The inguinal and femoral glands on the left were enlarged, grade 3 (on the basis of 4). The prostate was normal.

X-ray examination of the left tibia, July 24, 1945, showed chronic osteomyelitis of the shaft. Dental x-rays disclosed the mouth to be negative for periapical foci. There was grade 2 alveolar resorption in the upper left first molar area with pyorrhea pockets as well as grade 1 alveolar resorption about the lower anteriors. There was extensive caries in the upper right cuspid. A culture of material from the sinus in the left leg revealed the presence of hemolytic Staphylococcus aureus predominating.

The patient was referred to his dentist for treatment and then admitted to the hospital, Aug. 8, 1945 for penicillin therapy. A culture was taken from the sinus on August 18 and was sterile at the end of twenty-four and ninety-six hours. After a twelve day period of hospitalization he was discharged and the sinus appeared to be entirely healed. A protective dressing was applied and one week later, August 27, he was allowed to resume his normal activities. He was last seen by us on Oct. 9, 1945 and there had been no evidence of recurrence.

Case 2.—A man aged 37 with chronic osteomyelitis of both arms and legs was first known to us on June 4, 1945. Following an injury to his right knee in 1941 he had developed ostemyelitis in the right tibia, the left femur and fibula and the humeri. He had been hospitalized on numerous occasions and had undergone a total of forty-seven surgical procedures for this condition. (This represents the greatest number of operations for any patient in this series.)

---

[4] Petroff, S. A., and Schain, P.: The Enhancement of Bactericidal Properties of Well Known Antiseptics by Means of Detergents, Quart. Bull. Sea View Hosp. **5:** 372 (July) 1940.

Examination revealed a foul, irregular, ulcerating area of exposed bone, approximately 2 by 4 cm., over the anterior surface of the right tibia. Pus was draining freely from a sinus on the left thigh. There was moderate tenderness of the right shoulder, and the patient stated that in the past such tenderness had invariably indicated a breakdown.

X-ray examinations on June 5 revealed chronic osteomyelitis of the lower half of the posterior and mesial surfaces of the right tibia, chronic osteomyelitis of the lower half of the left fibula, chronic osteitis and osteomyelitis in the midportion of the left femur with some apparent activity on the anterior surface, chronic osteitis involving the shaft of the left humerus and early periostitis and medullary widening of the middle third of the shaft of the right humerus probably indicative of early activity. Dental x-rays showed no periapical foci. There were periodontal lesions, grades 2 to 4, with alveolar resorption and caries. Cultures taken from each leg on June 7 showed Staphylococcus aureus, moderately hemolytic and moderately pigmented.

The patient was hospitalized for penicillin therapy on June 17, after the dental sepsis had been eliminated. When he was discharged on July 6 each sinus was 95 per cent closed and the discharge decreased in like proportion. Wet tyrothricin dressings with compression bandages were applied to the wound on the left thigh, and the thin, watery discharge gradually dried up altogether. The area of exposed bone on the lower part of the right leg was treated in the same way, and this healed promptly. It has remained covered and dry since. A culture of the thin discharge from the left femur, taken August 3, revealed a very scant growth of Staphylococcus albus, one colony being slightly hemolytic. On August 9 additional material was obtained for culture by injecting a needle deeply into the sinus, which was apparently healed and a direct smear was negative. Cultures of September 11 were reported as negative after seventy-two hours.

In this, as well as in other similar cases with long sinuses extending from the skin to the bone, we attribute the slowness in healing to fibrosis between the skin and the bone. They respond well to wet tyrothricin dressings and compression bandages.

Case 3.—A man aged 32, a dental laboratory technician, first seen by us June 22, 1945, fell in 1925, injuring his right hip. A few days later he developed scarlet fever and two weeks later the right hip became stiff. He was then hospitalized and treated with traction and casts for a period of eight months. He left the hospital with a deformity of the right hip and has had recurrent bouts of pain and fever since. In 1930 he had an operation to correct the deformity, and this procedure was followed by more traction and casts. The wound drained for a few months, then healed and remained closed for three years. Since then (1933) however there has been intermittent drainage. An osteotomy was done in 1942.

Examination revealed an old operative scar 20 cm. in length over the right hip. In the upper portion of this scar, directly over the greater trocanter of the right femur, there was a deep, draining sinus 5 cm. in length which could easily be probed to the bone. There was a slight discharge from the left ear, which the patient stated he had had since the age of 10 years. The tonsils appeared to be infected, grade 2, but there was no history of tonsillar sepsis. The prostate was slightly indurated and irregular.

X-ray examination of the right hip June 28 demonstrated complete fusion of the hip joint, probably the result of old osteomyelitis. The dental x-rays disclosed alveolar resorption and periodontal foci, grades 2 to 3, and caries, grade 4. A prostatic smear revealed a few white blood cells with no clumps. Culture of the material from the draining sinus, taken before therapy was instituted, showed hemolytic Staphylococcus aureus with golden pigmentation and good hemolysis at forty-eight hours.

The dental work was attended to and the patient was hospitalized on August 20. He received 8,000 units of calcium penicillin to 1 cc. of the Aerosol O. T. 0.1 per cent in the topical application. Cultures taken eight and ten days respectively after treatment started remained sterile at ninety-six hours. When he left the hospital, September 2, the sinus tract was healed and dry and has remained so. He was last seen on Oct. 5, 1945. It is interesting to note that he no longer complains of discomfort in the affected area during damp weather.

Case 4.—A schoolgirl aged 17 years, who had osteomyelitis of the left hip for eleven years, was first examined at the clinic on June 11, 1945. She presented a history of severe mastoiditis at the age of 6 years on the right side, which required mastoidectomy, and immediately after operation she developed pain in the left hip. In the eleven years since this episode she had undergone twelve surgical operations and there had been a persistent draining sinus which closed intermittently. At one period it remained closed for seventeen months. However, for the past seven months there had been constant drainage.

Examination revealed scars on the left groin and the outer surface of the left hip. There was a draining sinus in the upper third of the anterolateral surface of the left thigh. The pelvis was rotated, with a spinal curvature compensating for 1¼ inch shortening of the left leg. The left thigh was smaller, grade 2, than the right, and the left inguinal glands were enlarged, also grade 2. Except for dental sepsis, examination was otherwise negative.

The dental x-rays showed a retained root fragment and one crowned tooth of questionable vitality; there was interproximal caries, grades 1 and 2. X-ray examination of the left hip demonstrated complete destruction of the joint, including the head and neck of the femur. There was solid bony ankylosis of the upper shaft and acetabulum. A culture of material from the sinus taken on the date of her first visit revealed Staphylococcus aureus, slightly pigmented and moderately hemolytic, and Streptococcus pyogenes.

The patient was given liver, vitamin B and iron therapy to correct a mild anemia (hemoglobin 11.7 Gm. per hundred cubic centimeters, or 78 per cent) and referred to her dentist for elimination of the dental sepsis. The dental work completed, she was hospitalized on August 30 and received the usual therapy except that 8,000 units of calcium penicillin was used to 1 cc. of the wetting agent for the local application. In order to increase the efficacy of the penicillin an opening about 3 cm. was made at the upper end of the sinus tract in the left thigh about 18 cm. from the lower end of the tract to enable the solution to enter the infected area more directly.

Culture of material from each sinus taken two days before discharge from the hospital revealed Escherichia coli, a few staphylococci, no hemolysis and no pigment. When she left the hospital on Sept. 15, 1945 the sinuses were closed, although the upper one was slightly inflamed. Wet tyrothricin dressings with compression were applied to this area, which cleared up within five days.

Case 5.—A bedridden man aged 70 was referred to our care and hospitalized on Aug. 26, 1945 for penicillin treatment of chronic osteomyelitis. In February 1934 he had developed pneumonia with subsequent persistent low grade fever. The right hip became inflamed, and incision and drainage were done. The right hip continued to drain, and in 1935 he was again hospitalized and operation was carried out. There were apparently multiple sinuses in the area of the upper part of the right leg, and the drainage continued to be almost constant. He had failed to respond to sulfonamide treatment.

X-ray of the pelvis and the right hip on August 27 disclosed the left half of the pelvis intact. The left hip joint showed no pathologic condition. The sacroiliac joints were not abnormal. The right femoral head and neck showed considerable decrease in size. The acetabulum was fairly well developed but high in position. The head and the femoral neck, although decreased in size, showed smooth borders. There was moderate increase in density in the ilium and ischium, in the acetabular region and also in the wing of the ilium. There were suggestive areas of bone destruction, particularly in the lateral region. The superior border of the acetabulum showed some hypertrophic changes. There was moderate soft parts swelling about the hip region. Moderate arterial calcification was present. A culture taken from a sinus on August 28 revealed gram negative bacilli, coli group; also diphtheroids. This patient also received 8,000 units of the calcium penicillin to 1 cc. of the wetting agent for the topical application. Another culture taken on September 13 was sterile at twenty-four and ninety-six hours. The patient was discharged on September 13 and the sinuses have remained dry since.

The bacteriologic findings show that the organisms present here were penicillin resistant and therefore, on the basis of these findings alone, penicillin therapy would not have been indicated. The clinical effects obtained may have been due to the interaction of the penicillin and the detergent on the bacterial cell.

Case 6.—A woman aged 27, a secretary, first seen by us on June 19, 1945, developed acute osteomyelitis of the left tibia following an injury at the age of 8 years and had suffered a draining sinus in this area since. During this interval she had undergone nineteen surgical operations. The patient was obese and stated that she had frequent sore throats. Her general condition was otherwise satisfactory.

Examination revealed operative scars over the entire length of the anterior tibia on the left leg with two sinuses, one about 1 mm. and the second about 2 by 1.5 cm. in diameter, about 5 cm. below the patella on the inner aspect. There was an area of ulceration about the sinuses. There was evidence of tonsillar and dental sepsis.

X-ray examination of the left tibia on June 20 showed chronic osteomyelitis at the upper half. Dental x-rays confirmed the presence of grade 4 (basis 4) caries. A culture taken on June 20 of material from the sinus revealed a heavy growth of beta hemolytic streptococci and some Pseudomonas pyocyanea organisms.

The patient was referred to her dentist, tonsillectomy was also done and on August 26 she was hospitalized for penicillin therapy. After a ten day course she left the hospital with a slight discharge from a pinhole opening about the old sinus area. The ulcerated area about the sinuses cleared up with application of chlorophyll ointment and is now (Oct. 29, 1945) entirely dry.

Case 7.—A man aged 40, a sales manager, first seen by us on April 2, 1945, presented the complaint of intermittent discharge from a sinus on his right hip. In 1921 he fell and injured his right hip. One year later he had severe pain in the lower part of the left leg with fever. A diagnosis of osteomyelitis of the left tibia was made. He was hospitalized and operated on at that time; one year later the bone was curetted. The wound drained for eight months and then healed and remained so until 1941, when he was again hospitalized for surgery. Since then the wound had not remained closed for longer than six weeks at any one time.

Examination revealed a scar running the entire length of the left tibia with a draining sinus at the distal portion and another scar over the right hip. There was evidence of dental and tonsillar sepsis; the prostate was symmetrical and slightly indurated.

X-ray examination of the lower part of the left leg on April 3, 1945 showed chronic osteomyelitis and osteitis involving the entire shaft of the left tibia. Dental x-rays revealed the presence of four devitalized teeth with root canal fillings and large radiolucent areas at the apexes. There were chronic alveolar abscesses and periapical infection, grade 4. Prostatic smear demonstrated from 5 to 8 white blood cells per high power field, with no clumps. Culture of material from the sinus taken on April 3 gave an abundant growth of hemolytic staphylococci.

The dental sepsis was eliminated and the patient hospitalized on May 22, 1945. Therapy was completed and he was discharged on June 2, 1945 with the sinus completely healed and dry. Another culture taken June 1, 1945 remained sterile at one week.

The patient was last seen on Oct. 22, 1945. He reported that a few days earlier he had noted a slight watery discharge in the region of the old sinus. Examination showed that this was not in any way associated with the old bone condition. Tyrothricin ointment was applied, and this superficial skin ulceration cleared up promptly.

SUMMARY AND CONCLUSIONS

1. Of 7 cases of chronic osteomyelitis involving the extremities, in 3 the hip was affected with either complete ankylosis or limitation of movement. Individual treatment consisted of hospitalization for a period of from ten days to three weeks with intramuscular penicillin (we have used both the sodium and the calcium salt) varying from 10,000 to 20,000 units every three hours. In some cases from 20,000 to 50,000 units were used for the first four doses. Simultaneously from 4,000 to 20,000 units of penicillin per cubic centimeter was applied locally into the sinus tract with 1:1,000 Aerosol O. T. (dioctyl ester of sodium sulfosuccinate) or Tergitol 4 (sodium tetradecyl sulfate) in isotonic solution of sodium chloride. The local application of penicillin to the site of infection was made at regular three hour intervals with quantities of solution up to 4 cc. retained in each sinus cavity either by drainage or with a compression bandage. The drainage method was accomplished by placing the patient in such a position that the sinus, from its cutaneous opening, would be uppermost, thereby allowing the solution of penicillin and wetting agent to seep down by gravity to the area of infected bone. When this was not possible, petrolatum gauze dressings were placed over the sinus after the solution had been injected.

2. We have had one definite failure and in a subsequent publication will present data emphasizing the importance of tracing the location of the sinus opening to the bone with contrast mediums and securing, with minimal surgical intervention, an opening in the sinus directly over this, enabling the optimum amount of solution to reach the infected bone. The simplicity of this principle is demonstrated in case 4, in which the draining sinus was 30 cm. from the infected bone. Prompt results were obtained as soon as the upper portion of this sinus, nearest the primary infection, received adequate penicillin.

3. Considered cosmetically, the nonoperative method of treating chronic osteomyelitis appears preferable to the older technic of saucerization or sequestrectomy, with its attendant mutilation and prolonged hospitalization. In this series alone there had been a total of ninety-one previous operations without any clinical cure.

4. The removal of all sources of focal infection preparatory to treating patients with penicillin-detergent is believed to be of vital importance.

5. Among war casualties, the high morbidity associated with osteomyelitis of the extremities may be substantially reduced if the effectiveness of nonoperative treatment is borne out by wider clinical experience.

Expectation of Life.—It has been estimated that the average expectation of life, at birth, in 1800 was 35 years, and the average woman of childbearing age had eight children born to her. By 1944 these ratios had changed to a life expectancy at birth of approximately 65 years. By 1944 also the average woman who had passed the childbearing age had had 2.2 children instead of 8. The crude death rate during the same period, 1830 to 1940, dropped from 25 (estimated) to the vicinity of 10, and the birth rate from an approximate 55 in 1880 to 20 in 1944—Smillie, Wilson G.: *Preventive Medicine and Public Health*, New York, Macmillan Company, 1946.

SURGICAL TREATMENT OF SPONTANEOUS NONTRAUMATIC HEMATOMAS

MICHAEL SCOTT, M.D.
Philadelphia

The symptomatology of massive intracerebral hemorrhage caused by hypertension is well known. The hopeless outcome in this condition following medical treatment prompted Cushing[1] in 1903 to report surgical therapy in 2 cases. He stated: "In spite of the unfavorable result following operation in both cases, the temporary amelioration of the severe symptoms is a sufficient justification for future attempts to afford surgical relief to certain carefully selected cases of intracerebral hemorrhage."

Since Cushing's article there have been many reports of successful removal of traumatic and spontaneous intracerebral hematomas from the cerebrum and cerebellum.

This paper is limited to spontaneous, nontraumatic hematomas of the left temporal lobe, since these lesions produce a clear, easily recognized clinical syndrome and are amenable, because of their location, to successful evacuation by trephine or craniotomy.

Russell and Sargent,[2] Bagley,[3] Penfield,[4] Craig and Adson,[5] Furlow, Carr and Wattenberg,[6] Pilcher[7] and Rowbotham and Ogilvie[8] have all reported successful results following evacuation of clots in this lobe as well as other cerebral areas. I present the following 3 cases:

Case 1.—L. D., a white man aged 53, referred by Dr. S. W. Eisenberg to the neurologic service of Dr. Sherman F. Gilpin Jr., Temple University Hospital, on Feb. 20, 1944, had an attack of weakness and vomiting two days before admission to the hospital. His wife stated that he "talked funny" and that his speech was difficult to understand. He became irritable and progressively drowsy and was hospitalized.

There was no history of head trauma. The patient had complained of headaches for almost a year and had often vomited in the morning. One month before the present attack he had "influenza" and was told that his blood pressure was "210." The family history was not obtained.

The temperature was 98.4 F., pulse rate 70, respiratory rate 18 and blood pressure 206/96. The patient was drowsy but easily aroused, when he showed a mixed aphasia with jargon speech. Tests for nuchal rigidity were not made. The pupils were equal and reacted sluggishly to light. The eyegrounds showed no choke or hemorrhages. There was a grade 1 sclerosis. A right homonymous hemianopsia was present with macular preservation (Dr. Hosner). The patellar reflex was increased on the right and a Babinski sign was present on this side. A weakness of the lower part of the face was also present on the right. There was no impairment of sensation (corroborated on later examination). The patient was right handed.

The red blood cell count showed 16 Gm. of hemoglobin and 5,630,000 red cells. The white blood cell count was 14,800, with 64 per cent polymorphonuclears, 26 per cent lymphocytes and 3 per cent eosinophils. The urinalysis was not abnormal. The blood Wassermann and Kahn reactions were negative. The sedimentation rate was 18 mm. in one hour. Spinal puncture showed a pressure of 130 mm. of water. The fluid was clear and contained 9 white cells. The protein was 66 mg. per hundred cubic centimeters. The spinal fluid Wassermann reaction was plus, minus, doubtful. The colloidal gold curve was 0023311000.

Another spinal puncture nine days later showed a pressure of 100 mm. of water. The fluid was now xanthochromic and contained only 1 white cell. The protein had increased to 77 mg. per hundred cubic centimeters. The Kolmer Wassermann reaction was negative and the colloidal gold curve 0122210000.

X-ray of the skull showed a shift of the pineal gland 6 mm. to the right and slight erosion of the internal table of the skull in the parietal area (fig. 1). X-ray of the chest was negative (Dr. S. S. Peoples).

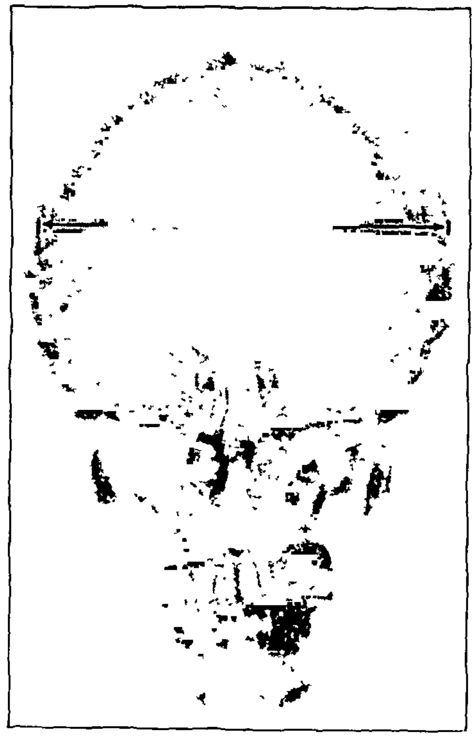

Fig. 1 (case 1).—Note the shift of the pineal gland 6 mm. to the right of the midline, indicating a space-taking lesion in the left cerebrum.

A diagnosis was made of a space-taking lesion in the left temporoparietal lobe, and the patient was transferred to the neurosurgical service. Before operation the patient was conscious and cooperative but still showed the neurologic changes reported on admission. On March 17 a left osteoplastic flap was reflected under solution of tribromoethanol local procaine and pentothal anesthesia. The x-ray report of an erosion of the inner table of the skull proved to be an area of increased vascularity of the inner table not directly over the lesion in the temporal lobe. The gyri over the posterior temporal lobe were pale and widened, the cortex in the posterior superior portion of the lobe was bluish and brownish (figs. 2 and 3). Palpation of this area revealed softening and fluctuation. A cannula was inserted and encountered black, tarry liquid blood at a depth of 1.5 cm. The cortex was incised and a large black hematoma, the consistency of cranberry jelly and the size of an orange, was removed. The remaining cavity appeared to fill the entire posterior half of the temporal lobe and to extend upward and posteriorly, slightly into the parietal and

occipital lobes. What appeared to be a membrane in the floor of the cavity was incised, and it was realized that the ventricle had been entered. There was no free bleeding from this cavity. The dura was closed and the bone flap replaced.

The histologic report was that the specimen presented no evidence of tumor, being composed of blood clots.

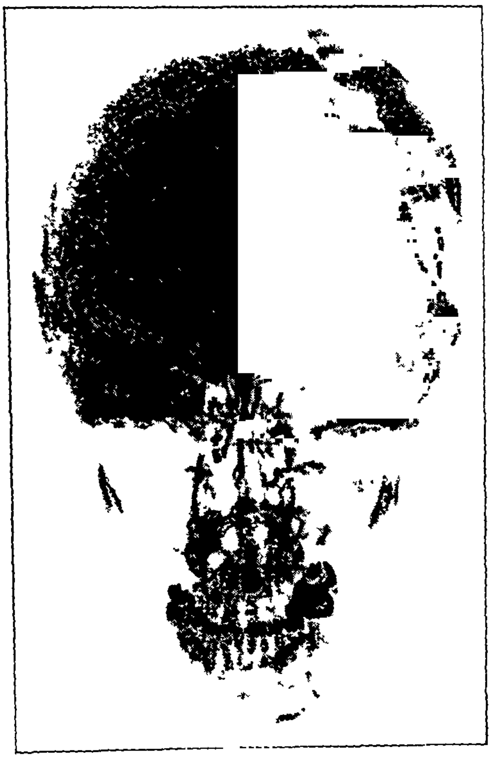

Fig. 2 (case 1)—Postoperative appearance. Silver clips outline softened cortex in the left temporal lobe immediately above the hematoma.

The patient convalesced well and was walking about at the time of discharge on March 29. There was still a mixed aphasia present and a complete right homonymous hemianopsia.

The patient was examined in January 1945, approximately eleven months after onset and ten months after operation. He had no headaches, the aphasia had improved considerably and was evident only when the patient was excited or nervous, and the right homonymous cut was still present. The blood pressure was 190/110.

Case 2.—E. W., a Negro woman aged 40, admitted to the neurologic service of Dr. A. S. Tornay at the Philadelphia General Hospital on Aug. 4, 1944, while working in a laundry was seized with a sudden, severe pain in the left side of her head. Within the next twenty-four hours weakness of the right arm and leg developed and the patient was admitted to the hospital.

There was no history of head trauma. The patient had been complaining of headaches, which were gradually getting worse. The family history was negative for any cerebral accidents.

On admission the temperature was 100 F., pulse rate 64, respiratory rate 18 and blood pressure 140/80. The patient was drowsy but could be aroused and was cooperative. Anomia and jargon speech were present. There was no nuchal rigidity. Examination of the eygrounds showed no choke and no vascular lesions. There was pronounced weakness of the entire right side of the body. The patient was right handed. The complete blood count and urinalysis were not abnormal. The urea nitrogen was 16 mg. per hundred cubic centimeters, the blood sugar 112 mg. per hundred cubic centimeters. The blood Wassermann reaction was negative on two occasions. X-ray of the skull was negative. The pineal gland was not calcified. X-ray of the chest was negative. An electrocardiogram was negative.

Seventeen days after onset, the patient showed a gradual improvement in speech and motor power. Twenty-five days after onset, routine examination of the eyegrounds showed a choked-disk of 2 diopters. The following day a spinal puncture showed xanthochromic fluid under a pressure of 380 mm. of water. Recheck examination twenty-six days after onset showed the presence of sensory mixed aphasia, weakness of the entire right side of the body and no impairment to pain, temperature, touch or vibration sense. Position sense was present in the legs and difficult to test for in the right upper extremity. The deep tendon reflexes were active on both sides. A Hoffman sign was present on the right. Babinski's sign was absent.

Recheck spinal puncture twenty-seven days after onset showed a pressure of 350 mm of water. The spinal fluid showed 8 cells; protein was 50 mg. per hundred cubic centimeters The serologic and colloidal gold tests were not reported

Recheck eye examination thirty days after onset showed no cooperation to visual field test. There was 2 diopters of choked disk in both eyes. A few small hemorrhages were present on the disk. There were none in the periphery of the retina The arteries were small and sclerotic (Dr. J. C Siggins).

The patient's headaches became severe again forty days after onset and surgical intervention was requested.

A preoperative diagnosis was made of hematoma or abscess of the left temporal lobe, and a left exploratory craniotomy was done on September 20, approximately seven weeks after onset of symptoms. The blood pressure before operation was 142/80.

The gyri of the left temporal lobe were wider than usual, and the cortex in the posterior superior portion was yellowish brown. A cannula was inserted in this area and black, tarry liquid blood was aspirated. The cortex was incised and a solid hematoma the size of a small apple removed There was evidence of recent and old bleeding. A biopsy was also taken of material from the floor of the cavity. A small portion of choroid plexus of the lateral ventricle protruded into the depth of the cavity. It was not bleeding, and there was no flow of any ventricular fluid. I could not determine whether the wall of the ventricle had been perforated at operation or the clot had broken into the ventricle. The cortical rim of the cavity was marked with silver clips, and a clip was placed into the deepest portion of the wall (figs. 4 and 5) The biopsy was reported by Dr. Helena E. Riggs as organizing hematoma There were no tumor cells.

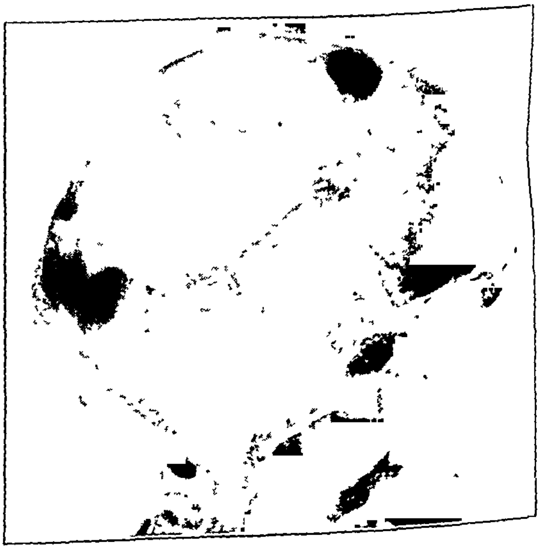

Fig 3 (case 1)—Lateral view

The patient improved rapidly following operation and on the eighth day she was sitting up and jargon speech had disappeared Eighteen days later the patient complained of recurring headaches. Spinal tap showed clear fluid under 100 mg. of water pressure. The blood pressure was 130/75. The patient was placed on restricted fluids and hypertonic enemas, and headaches decreased.

The patient left the hospital twenty-one days after operation. The jargon speech had disappeared, but she still complained of headache at times. No follow-up could be secured.

CASE 3.—H. S., a white man aged 37, was admitted to the medical service of Dr. Mitchell Bernstein at the Jewish Hospital on Sept. 9, 1944. The patient's wife stated that he had been drowsy and, at times, irrational for twelve hours prior to admission.

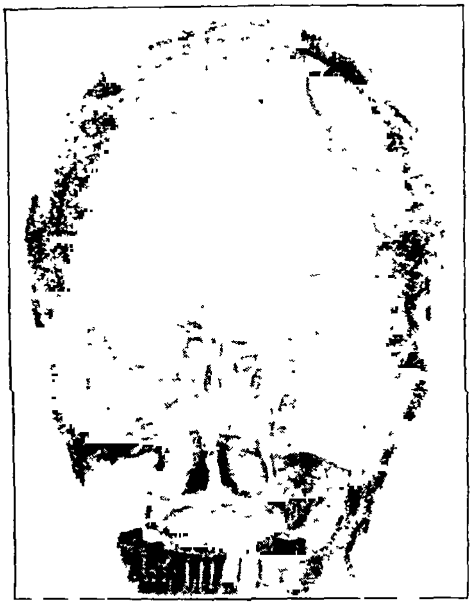

Fig. 4 (case 2).—Postoperative appearance. Maximum point of lesion, presenting on the cortex of the left temporal lobe, outlined by silver clips. Compare this area with figures 2, 6 and 7. Silver clip in floor of cavity shows mesial extension of hematoma.

Fourteen days before admission the patient had complained of constant pain over the left eye and was treated for a frontal sinusitis. No elevation of temperature was present at that time. This pain decreased and the patient was comfortable until the day preceding admission, when during intercourse he suddenly developed a severe pain over the left eye and speech became thick and unintelligible. He rapidly became irrational and drowsy and was admitted to the hospital approximately twelve hours after the onset of the acute head pain. The past history was negative for any serious illness or previous severe headaches. There was no history of head trauma.

The blood pressure on admission was 130/80, the pulse rate 48, the respiratory rate 18 and the axillary temperature 96 F. The patient was very drowsy. He responded to a few commands but did not answer any questions. Slight nuchal rigidity was present. His face was plethoric and there was slight cyanosis of the lips and nails. The right pupil was larger than the left, and there was ptosis of the left upper lid. The Babinski sign was present bilaterally. A provisional diagnosis was made of spontaneous subarachnoid hemorrhage or meningitis. The patient was right handed.

A spinal puncture showed an initial pressure of 300 mm. of water. The fluid was homogeneously pink. There were 1,500 red cells and 10 white cells. The total protein was 100 mg. per hundred cubic centimeters. The spinal fluid Wassermann reaction was negative and culture was sterile. The blood Wassermann test taken on the day of admission was negative. The hemoglobin on two occasions was 15.4 and 14.7 Gm. and the total red blood cells numbered 5,400,000 and 5,210,000. The white blood cell count on admission was 13,000, with 96 per cent polymorphonuclears, 2 per cent lymphocytes and 2 per cent monocytes; the following day it was 14,900, with 72 per cent polymorphonuclears, 25 per cent lymphocytes and 3 per cent monocytes. The blood sugar on two occasions was 110 and 100 mg. The blood urea nitrogen was 11 mg. and 10.5 mg. The carbon dioxide combining power was 44. The sedimentation rate was a diagonal curve, 17 mm. in one hour. Cultures of the nasopharynx showed Bacillus subtilis, Streptococcus viridans and hemolytic Staphylococcus albus. Blood culture was reported negative. The bleeding time was three and one-half minutes, the coagulation time two and one-half minutes and the prothrombin time 30 per cent of the normal control. The vitamin C blood level was 2.0 mg. per hundred cubic centimeters. The purified protein derivative number was subsequently reported as negative.

Nose and throat examination by Dr. Sacks Bricker suggested chronic ethmoiditis but no evidence of acute suppuration in the frontal sinus.

Neurosurgical examination the day after admission revealed a drowsy patient who could be aroused. A mixed aphasia with jargon speech was present. There was nuchal rigidity. There was a ptosis of the left upper lid. The patient winced when the left temporal area was pressed on or percussed. The eyegrounds showed no choke, hemorrhage or exudate. There was no cooperation to the field test. There was weakness of the right lower third of the face and pronounced weakness of the right arm and leg. A Babinski sign was present on the right. The patient winced when pinched in either leg, but there was no cooperation to sensory tests. These symptoms suggested a rapidly expanding lesion into the left temporal lobe, probably a hematoma. An aneurysm of the left circle of Willis, as well as brain abscess, was considered. A stereoscopic x-ray for pineal shift was requested. The patient was placed on 24 ounces (720 cc.) of total fluids in twenty-four hours. He was given 50 cc. of 50 per cent sucrose intravenously every two hours for three doses and a hypertonic magnesium sulfate enema every eight hours; vitamin C 100 mg. (subcutaneously) and vitamin K 8 mg. (subcutaneously) were given daily.

The patient was seen by the attending neurologist, who felt that he had a lesion in the left temporal lobe and that a cerebritis with a brain abscess must be ruled out.

The cardiac and general medical examinations were entirely negative. The electrocardiogram was negative. X-rays of the sinuses and chest were negative. The heart was slightly enlarged

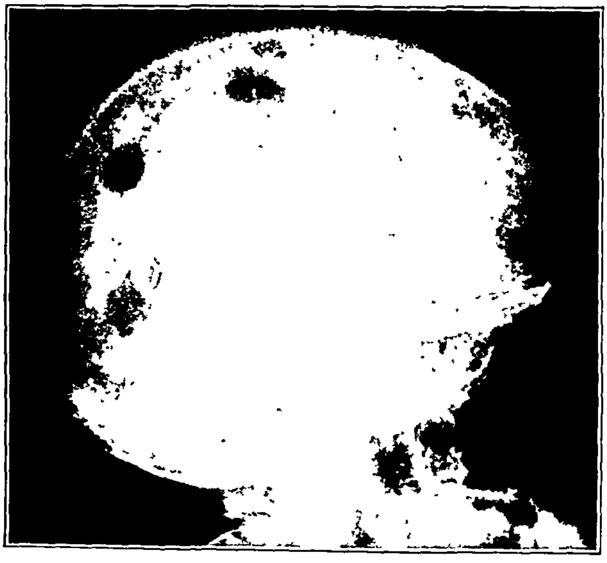

Fig. 5 (case 2).—Lateral view.

X-rays of the skull on the third day after admission showed a shift of the pineal gland to the right of the midline (Dr. Leon Solis-Cohen).

Following the dehydration measures, the patient improved considerably by the sixth day after admission. Spinal puncture at this time showed a clear fluid under 110 mm. of water pressure. There were no red cells and only 4 white cells. During the next six days the headaches again became severe, the patient became drowsy, operation was decided on and the patient was transferred to the neurosurgical service.

A left exploratory craniotomy was done on September 22, approximately thirty days after the initial onset of left supraorbital headache and sixteen days after admission to the hospital. The gyri of the superior portion of the left temporal lobe were flattened. A cannula was inserted and liquid black, tarry blood aspirated. The cortex was incised and a large semisolid clot, about 6 cm. in diameter, was aspirated by suction. When the clot was removed, the thin transparent mesial wall of the ventricle was seen and a small portion of the choroid plexus herniated through into the clot cavity. No bleeding occurred from the choroid plexus. There was no gross evidence of tumor. The cortical rim of the cavity was outlined with silver clips, the dura closed and the flap replaced (figs. 6 and 7).

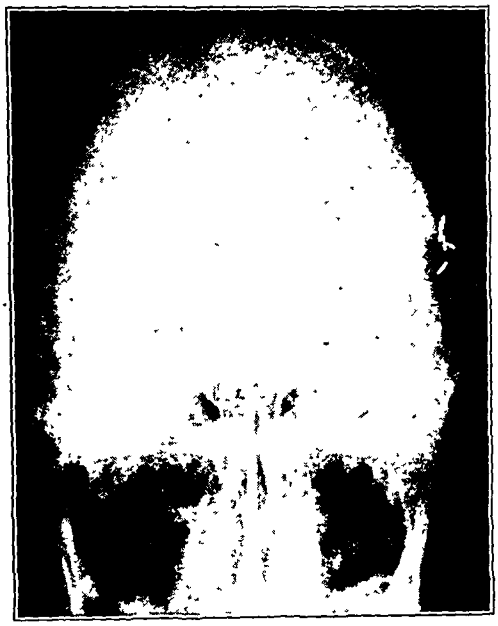

Fig. 6 (case 3).—Postoperative appearance, showing silver clips which outline maximum point of lesion in the cortex of the left temporal lobe. Note that this area is almost identical in all 3 cases.

Following the operation the patient's blood pressure ran between 170 and 120 systolic and 80 to 90 diastolic. The last five days before discharge it stayed at the 120/80 level.

The patient was fully well with no headache and slight jargon speech on discharge on October 18.

Recheck examination Jan. 2, 1945, approximately three and one-half months after operation, revealed that the patient had had no headache, speech was excellent, and there were occasional anomia and jargon speech when excited. A homonymous right inferior quadrant cut was present to the finger test. Muscle power was excellent. There was no impairment to pain, touch, warm or cool sensation, vibration, position sense or stereognosis. Blood pressure was 130/90.

COMMENT

The etiology of these hematomas is still obscure. Miliary aneurysm was suggested by Charcot and Bouchard in 1868; Von Monakow in 1905 believed that atheroma and hyaline degeneration should be considered. Ellis in 1909 stated that the lesion responsible was arteriosclerosis, beginning in the elastic layer, possibly involving all coats and resulting in aneurysm or simple rupture.[3] Pick in 1910, however, concluded "The importance of miliary aneurysms in the causation of hemorrhage has been exaggerated." Sachs,[9] however, believed that Pick's findings at least suggested some aneurysmal dilatation of the vessel wall as the cause for the hemorrhages.

Westphal believed that the actual hemorrhage was preceded by a period of ischemia, the result of angiospasm. During the period of spasm, the tissues surrounding the vessels were altered and after return of the blood into the vessels this tissue did not offer sufficient resistance to vessel wall and leakage occurred.[3] Against this theory might be cited the hundreds of attacks of homonymous hemianopsia that occur in certain migraine patients for years without a permanent field cut resulting.

Globus and Strauss believe that cerebral apoplexy is a final event and that it is preceded by softening.[4]

Marburg [10] made microscopic studies of cerebral hemorrhage in younger persons and concluded that these hemorrhages are due to toxic or toxic infectious changes in the walls of the blood vessels; that these changes remain latent for a considerable period of time but may lead to sudden increase in blood pressure and consequent hemorrhage through overexcitement or overwork or some other emotional factor.

A search for a clue as to etiology in 15 cases of intracerebral hematoma of the left temporal lobe (12 reported elsewhere and 3 cases reported herein) showed the following:

The blood Wassermann reactions were recorded in 7 cases and all were negative. Hypertension was present in approximately 40 per cent of the entire group. Pyogenic infection was not proved in any of the cases, although the white count and sedimentation rate were elevated at times. Trauma was carefully ruled out. Metabolic disturbances were not reported. Exogenous poisons were not reported, and little mention is made of the patient's occupation. Penfield reported a case in which the onset of symptoms came on after a 14 year old boy smoked his first pipe. He attributed the accident to the strain of vomiting rather than to the toxicity of the nicotine.

Congenital anomalies or aneurysms were not reported. These lesions could easily be missed during a brain operation, and only two autopsies were done in the entire group.

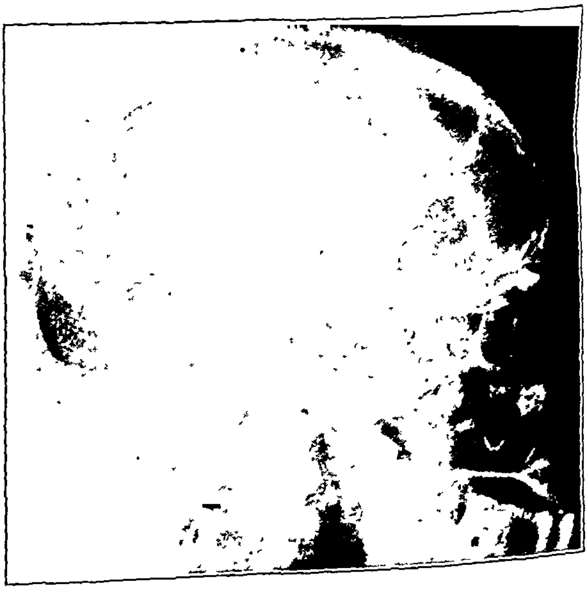

Fig. 7 (case 3).—Lateral view.

Brain tumor was not found as the primary cause in any of the cases. This is probably because such cases

10. Marburg, O.: Difficulties of Differential Diagnosis of Hemorrhage in Young Persons with Appearance of Brain Tumors and Encephalitis, Deutsche Ztschr. f. Nervenh. 105: 22, 1928.

would be reported as brain tumors complicated by or associated with hemorrhage rather than as spontaneous hematomas.

Blood dyscrasias were searched for in 1 case of my series and the only abnormality found was a prothrombin level of 30 to 37 per cent of normal and a slight increase in red cells and hemoglobin. This abnormality was not mentioned in the 12 cases reported by others.

Excitement or exertion appeared to be a precipitating factor in case 2, since severe sudden headache came on while the patient was working in a laundry and in case 3, when the sudden pain came on during sexual intercourse. Penfield, as stated previously, attributes the acute onset in a boy of 14 to severe vomiting following the smoking of his first pipe. Bagley reported a sudden onset in an overheated quarryman on a hot July day. Craig and Adson stressed strenuous exercise and severe emotional strain as possible precipitating factors in the nontraumatic cases.

Spontaneous intracerebral hematomas were most frequent between the ages of 30 and 50 (66⅔ per cent).

There were 8 males and 7 females, 13 white and 2 Negro. The symptoms and signs follow, in general, the pattern reported by Furlow and his associates.[6] The onset was sudden in 13 of the 15 cases. The presenting symptom in 10 was severe headache, usually frontal or occipital, at times on the side of the lesion and often associated with nausea and vomiting. The condition occasionally started with sudden unconsciousness or a convulsion. Some degree of aphasia, usually with anomia or jargon speech, was present in every case in which coma was not present. Nuchal rigidity was reported in 3 cases.

Irregularity of the pupils was reported in 3 cases, ptosis of the upper lid on the side of the lesion in 1. Ophthalmologic examination revealed hypertension or arteriosclerosis in 2 cases. Choked disk frequently occurred a few weeks after the onset. It was reported in 7 cases of the 15, slight in 5 cases (examined from the first day to the eighteenth day after the onset of the illness) and pronounced in 2 cases, 1 three weeks after the onset of illness and another six to eight weeks after onset.

A right homonymous hemianopsia was present in cases 1 and 3 of this series. Visual field examinations were reported in only 2 cases reported by others, and in 1 a right homonymous cut was found. The deep tendon reflexes were usually increased on the right and the Babinski sign was present on this side in 8 cases, and the Hoffman alone on the right in 2 cases.

Right sided paralysis to a varying degree came on within a few hours to a few days in 14 of the 15 cases (93 per cent). The face alone was involved in only 1 case. The arm and face were most involved in 2 cases.

Impairment of sensation was reported in only 2 cases of the entire series, and in these the parietal lobe was involved more than the temporal lobe.

The final fluid pressure was reported in 6 cases and found elevated in 4. The color of the fluid was recorded in 8 cases; it was clear in 1, blood tinged in 3 and xanthochromic in 4. The spinal fluid protein was increased in the 4 cases in which it was reported, regardless of the time of puncture from onset of illness. The protein varied from 50 to 100 mg., with an average of 72 mg. per hundred cubic centimeters of spinal fluid.

X-rays of the skull were done in all 3 cases of this series and the pineal gland was shifted to the right of the midline in 2 (cases 1 and 3). X-rays of the skull were reported in only 2 cases of the 12 taken from the literature. The pineal position was not mentioned. An encephalogram was unsuccessful in 1 case and a ventriculogram was diagnostic for a left sided lesion in another.

The time from onset of symptoms to operation varied considerably. The earliest period was three days and the latest nine months: 2 cases, first week; 7 cases, second to fourth week; 2 cases, fourth to fifth week; 3 cases, sixth to seventh week; 1 case, thirty-sixth week. From this it appears that early operation is not essential.

A left exploratory craniotomy was done in 13 cases and a trephine with aspiration in 2. The usual procedure was to tap the soft cortex, aspirate the liquid tarry blood, incise the cortex, remove the hematoma by suction and, as a precaution, take a biopsy of the hematoma and cavity wall as suggested by Furlow to rule out tumor. The site of the lesion in every case was *the posterior superior portion of the left temporal lobe* with some extension, at times, into the parietal and occipital lobes.[11] The gyri were often flattened and widened and soft to palpation. In 7 of 15 cases the cortex was stained a brownish yellow, a bile-tinged color (first reported by Penfield). The hematomas were all subcortical, often a few centimeters below the cortex and usually the size of a small orange. In over 50 per cent of the cases the cavity contained both tarry liquid blood and a larger amount of solid blood clot. A cyst wall was reported in only 1 case. The cavity in this case contained yellowish brown fluid and represented the end results of a hematoma, the operation being performed nine months after the sudden onset of a hemiplegia (Pilcher case 5).

Age of Onset

Age Group	Number of Cases
10-19 years	1
20-29 years	1
30-39 years	6
40-49 years	4
50-54 years	3

No evidence of tumor tissue was reported in any case. In the 3 cases in this series the thinned mesial walls of the lateral ventricle could be seen after the clot was removed. In 2 cases a tuft of the choroid plexus was found projecting through the wall into the cavity of the hematoma. This was probably an artefact produced by the suction. Penfield reported one clot as extending from the pia of the cortex to the wall of the ventricle, which was not entered but displaced.

---

[11] Naffziger also called attention to this area as being the most common site, in his experience, for both the spontaneous and the traumatic hematomas (discussion of Craig and Adson[8]). No definite reason could be found for the selective location of the hemorrhage. It appeared to me that this area is a terminal zone for the subcortical branches of the middle cerebral artery. The area probably receives little supply, if any, from the posterior cerebral artery. It may be that at this point the blood supply is at a minimum of efficiency. Should a disease process occur, the possibility of softening with resultant rupture of a small arteriole, and the production of a hematoma, must be considered. There is also a diversity of opinion as to whether the hemorrhage is of arterial or venous origin. Craig and Adson[8] favored the venous origin, since they noted that, after the clots were evacuated and the cavity explored, no active bleeding could be found. On the other hand, Rowbotham and Ogilvie[10] have reported that after the removal of the intracerebral hematoma in 2 cases they found, in the wall of the cavity, a small adherent clot plugging the mouth of the arteriole that was ruptured. They give no histologic evidence as to whether the plugged vessel was an artery or a vein. W. B. Hamby (Gross Intracerebral Hematomas, New York State J. Med. 45:866, 1945) recently reported 16 cases of intracerebral hematomas occurring in various lobes. One case was proved to be due to a ruptured aneurysm.

POSTOPERATIVE RESULTS

There were no fatalities in the 3 cases reported in this paper. The shortest follow-up in this series was of patient 2, twenty-one days, and she still complained of headaches at the time she left the hospital. Patient 1 was reexamined twelve months postoperatively. He works about his home. Jargon speech occurs at times when he is excited. A right homonymous cut is still present. Blood pressure was 190/110. Patient 3 was seen three and one-half months after operation, felt fine and had occasional jargon speech when excited. The homonymous cut had receded to an inferior homonymous quadrant cut. He had no motor or sensory disturbances. The blood pressure was 130/90. One month after this examination he had a generalized convulsion. Recheck examination six months after operation showed only a residual inferior right homonymous quadrantopsia. The patient felt well, he had no headaches or convulsions, his speech was excellent and he worked as a stock room clerk.

There were three fatalities in the 12 cases reported by various authors. Two of these patients were in coma when operated on and they had a blood pressure of 220/110 and 210/55. These were the highest blood pressures recorded in the entire series. One was operated on the fifth day after onset and the other the twenty-third day. In both cases autopsy showed a large clot still present in the temporal lobe with surrounding edema of the brain.

Of the 9 patients that survived operation, 5 showed various degrees of residual speech disturbances, 4 had some degree of paralysis and 1 had only a field cut. A residual visual field cut alone was present in 1 case (eight year follow-up) and some degree of hemiparesis alone was reported in 3 cases.

SUMMARY

Three cases of spontaneous hemorrhage into the left temporal lobe of right handed patients showed a group of symptoms falling into the following pattern:

1. Sudden onset with severe headache in 2 cases and an aphasia in the third.
2. Progressive drowsiness.
3. Focal symptoms of an expanding lesion in the left temporal lobe: (*a*) partial aphasia with anomia and jargon speech, (*b*) right homonymous hemianopsia, (*c*) increased deep tendon reflexes on the right, (*d*) Hoffman and Babinski signs on the right, (*e*) progressive weakness of the right side of the body, (*f*) no sensory disturbances, (*g*) shift of the pineal gland to the right.
4. The spinal fluid pressure was usually increased and the fluid was blood tinged, clear or xanthochromic. The total protein was increased above normal.

Following a left exploratory craniotomy, a subcortical hematoma was found in all 3 cases, in the left posterior superior temporal lobe. The clot was removed by suction, the dura closed and the bone flap replaced.

Recovery with improvement took place in all 3 cases.

A series of 12 similar cases reported by various authors fell into the same symptom pattern as the cases reported here.

No definite etiology could be found. Excitement and overexertion appeared to be precipitating factors.

Inadequate studies were made in most cases concerning exogenous toxins, blood dyscrasias, virus and other forms of infection.

CONCLUSIONS

1. Spontaneous, nontraumatic hemorrhage into the left temporal lobe produces a syndrome of an acute focal expanding intracranial lesion.
2. These cases are often erroneously diagnosed as "stroke" caused by cerebral arteriosclerosis or hypertension.
3. Any person, regardless of age, developing sudden headache associated with progressive focal signs such as aphasia, hemiplegia, anesthesias or visual field defects, vomiting and progressive drowsiness should be considered to have a space-taking lesion, possibly intracerebral hematoma. They should have the advantage of the following basic studies: (*a*) neurologic examination, (*b*) stereoscopic x-rays of the skull for pineal shift, (*c*) examination of the eyegrounds and perimetric fields and (*d*) careful spinal puncture for pressure, differential cell count, quantitative protein and Wassermann reaction.
4. Exploratory craniotomy with evacuation of the blood clot offers the best method of treatment in cases showing progression in signs and intracranial pressure.

DESENSITIZATION TO INSECT BITES

ALEXANDER HATOFF, M.D.
Oakland, Calif.

The return of servicemen from the far flung battlefronts of this global war has served to emphasize the problem of insect borne diseases. To date, most of the efforts of the sanitarian have been concentrated against the animal reservoirs of these diseases, and against the insect vectors of these diseases. Little has been reported on the immunity or resistance of the individual human host against the bites of insects.

Many laymen make the chance observation that at the beginning of the mosquito season they are bothered by mosquito bites. They then note that this becomes less troublesome as the season wears on. The same is true for flea bites.

The region surrounding the San Francisco Bay abounds in fleas. It is not surprising, therefore, to find references to experimental studies on the subject of immunity to flea bites emanating from this area. In 1939 Cherney, Wheeler and Reed[1] concluded that "if it is possible to induce 'immunity' against flea bites, it is probably likewise possible to 'immunize' against bites of other insects. If so, this would be an extremely valuable adjunct in the control of insect borne diseases." To prove their thesis that the selection of victims by fleas is not a matter of chance and that there is evidence of immunity to flea bites, these investigators actively immunized with flea antigen a group of 26 persons very susceptible to flea bites. The resultant immunity was demonstrated objectively in their series.

In 1941 McIvor and Cherney[2] described the technic of desensitization to flea bites. They used a polyvalent flea antigen prepared from whole fleas of the species Pulex irritans and Ctenocephalides canis. All patients

---

Miss Martha Eaton made the statistical analysis of data.

This investigation was supported by a grant from the Permanente Foundation.

treated were given a 1:5,000 dilution of the antigen. Children up to 5 years of age were given 0.1 cc. on the first injection and 0.2 cc. for the remainder of a course of three inoculations. Initial inoculations for patients over 5 years of age consisted of 0.2 cc., which was increased to 0.4 cc. on the second injection and maintained at 0.4 cc. for the remainder of the course of six injections.

Beneficial results from the administration of flea antigen to susceptible persons consisted in smaller size of the incised wheal, shorter duration of the wheal and decrease of irritation and of pruritus. Some patients in McIvor and Cherney's series benefited from the first injection, others not until after the fifth or sixth injection. Some were relieved for two to three months, others were relieved permanently. In none of those treated with flea antigen could circulating antibodies or precipitins be demonstrated in the blood.

In 1943 McIvor and Cherney[3] gave flea antigen to 92 patients whose hypersensitiveness to flea bites was evidenced by urticarial reactions or asthmatic attacks as a result of flea bites. All benefited but 5, and 1 child was made worse by flea antigen.

In the present series 129 susceptible infants and children were given 136 courses of injections in an effort to determine objectively the effect of flea antigen on the duration of symptoms, presence of a wheal, irritation, pruritus and secondary infection. Each child served as his own control, since in each of these patients the symptoms had continued unabated for a period of from one week to one year.

The flea antigen used was the product prepared by the method developed by Reed and his associates. It consists of an extract of the whole fleas of cat, dog and human beings (Ctenocephalides felis, Ctenocephalides canis and Pulex irritans) in phenolated isotonic saline solution. An attempt was made to give children up to 5 years of age 0.1 cc. of flea antigen for the first injection and 0.2 cc. for the remainder of a course of at least three inoculations. For children over 5 years of age an attempt was made to give an initial subcutaneous dose of 0.2 cc. and 0.4 cc. for at least five subsequent injections given every other day. The course was repeated as indicated.

[3] McIvor, B. C., and Cherney, L. S.: Clinical Use of Flea Antigen in Patients Hypersensitive to Flea Bites, Am. J. Trop. Med. **23**: 377-379 (May) 1943.

The cases have been grouped in three tables according to the results obtained. Table 1 includes patients benefited by flea antigen. Table 2 includes the group whose benefit from flea antigen was equivocal. Table 3 consists of the group who received no benefit from flea antigen.

COMMENT

One hundred and twenty-nine susceptible infants and children, all living in the southern area of Richmond, Calif., were immunized against flea bites by the method of Reed and his associates. Of these, 100, or 78 per cent, were benefited. Six patients, or 5 per cent of the total, received equivocal benefit. Twenty-three, or 17 per cent, failed to respond.

The average age of these patients was 4 years. Of the 129, 68, or 50.4 per cent, were females, and 64, or 49.6 per cent, males. There were only 2 colored patients in the entire group (1.6 per cent), even though the colored group in the general population here is much higher.

Sixty-one patients offered data regarding duration of symptoms. Twenty-six patients (43 per cent) had symptoms from one week to one month before therapy. Twenty-five patients (41 per cent) had symptoms from one month to one year before the institution of flea antigen. Ten patients (16 per cent) gave a history of relative symptoms of over one year preceding therapy.

The presence of an incised wheal was observed in 109 patients (84 per cent). Of these, 3 had papules only, 1 had a bullous reaction and 3 had definite urticaria. In 20 patients (16 per cent) no wheal was seen. All patients had irritation and pruritus. Secondary infection was noted in 20 patients (16 per cent). Of these, 3 had impetigo contagiosa.

In treating these patients, the average number of injections of flea antigen given was four. The average time of response following the initial injection was eight days.

CONCLUSIONS

In a series of 129 susceptible infants and children, 4 out of 5 were benefited by the use of flea antigen. This constitutes a demonstration of one method of developing host immunity to insect bites. The importance of this demonstration lies in the possibility of the use of such a method as an adjunct in the control of insect borne diseases.

Common Errors in Statistical Interpretation of Medical Data.—Current medical literature is made up in great part of an analysis and an interpretation of clinical data: often a series of cases of a newly observed syndrome is reported. In other circumstances a study is made of the effect of a new surgical technic; frequently new methods of treatment are devised. These observations that have been made so painstakingly require suitable statistical analysis and interpretations. Are the results that have been secured of real significance or might the same results have been obtained by chance variation?—Smillie, Wilson G.: Preventive Medicine and Public Health, New York, Macmillan Company, 1946.

Clinical Notes, Suggestions and New Instruments

ACUTE OSTEOMYELITIS IN A NINETEEN DAY OLD INFANT

LIEUTENANT BERNARD H. SHULMAN (MC), U.S.N.R.

This is a report of a case of acute osteomyelitis in a 19 day old infant. Cases of osteomyelitis in childhood are not unusual but it is felt that the occurrence of this condition during the neonatal period is rare and worthy of recording. In addition, the therapeutic value of penicillin is demonstrated in controlling the acute phase of the infection.

REPORT OF CASE

D. D., a white boy aged 19 days, was admitted as a Navy dependent to the pediatric service of the Newport Hospital, Newport, R. I., because of elevated temperature and swelling of the left thigh of two days' duration.

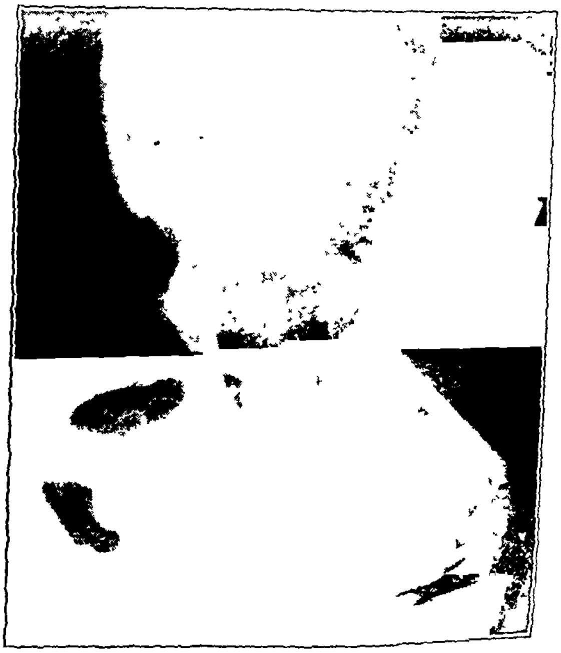

Fig. 1.—Appearance at time of admission, showing soft tissue swelling around the left femur. There is no evidence of pathologic change in the bones.

The infant was born at full term by spontaneous delivery and weighed 7 pounds 1 ounce (3,200 Gm.). He had an uneventful, afebrile, neonatal course in the nursery and was discharged on the ninth day of life after having reached birth weight. His formula consisted of an evaporated milk, water, dextrimaltose mixture.

The mother stated that the child seemed to cry when he was handled, shortly after reaching home. However, he took his formula readily and there were no visible signs of infection. Two days before admission, at the age of 17 days, the infant became restless, fed poorly and developed a fever of 102 F. At this time a swelling of the left thigh was observed, and two days later, at the age of 19 days, the child was admitted to the hospital.

On entry the child appeared acutely ill. The temperature was 100 F., the pulse rate 136 per minute and the weight 8 pounds 3 ounces (3,714 Gm.). Physical examination was negative except for the findings of the left leg. There was swelling of the left thigh, with tenseness and moderate fluctua-

tion in the outer aspect. The leg was held in abduction and external rotation, with flexion at the hip and knee. The child cried with any attempt to move the affected leg actively.

The suspected deep abscess was aspirated and a small amount of green pus was obtained. Smear of this material showed many pus cells but no organisms. Culture of the material revealed unidentifiable gram-positive organisms.

On admission the white blood cell count was 21,200, with 72 per cent polymorphonuclears, 14 per cent lymphocytes and 14 per cent monocytes. The hemoglobin was 100 per cent and the red blood cells 3,500,000 per cubic millimeter. The urine was normal. An x-ray (fig. 1) taken shortly after admission showed soft tissue swelling at the upper part of the left leg There was no evidence of pathologic changes in the bones.

On the second hospital day 10 cc. of thick green pus was obtained by incision of the fluctuant, swollen thigh. Culture of this material revealed a pure growth of nonhemolytic Staphylococcus aureus. A blood culture, obtained with difficulty on the same day, was positive for nonhemolytic Staphylococcus albus This was felt to be a contaminant

Treatment was instituted immediately on hospitalization. Penicillin was given intramuscularly in doses of 10,000 units every three hours. In addition, local hot compresses were applied to the swollen thigh. The child received 40,000 units of penicillin on the first day and 80,000 units daily for the next seven days. On the ninth and tenth hospital days the child received 20,000 units daily. On the eleventh day the drug was discontinued. In all, the patient received 640,000 units of penicillin.

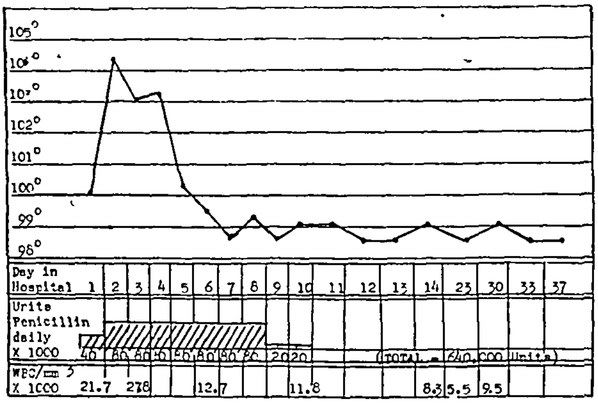

Fig 2—Course in the hospital

During the course of therapy the condition of the child improved remarkably. The temperature, which ranged from 100 to 104 F. during the first four days, returned to normal on the sixth day and stayed normal during the remainder of the period of hospitalization, as shown in figure 2 Frequent white blood cell counts showed a steady decline from a leukocytosis of 27,800 on the second day to 8,350 on the ninth day, with concomitant reduction of polymorphonuclears. The red blood cell count remained at approximately 3,500,000 per cubic millimeter.

A second x-ray (fig. 3), taken on the ninth hospital day, showed periosteal reaction and osteomyelitis of the upper third of the left femur. On the twenty-second hospital day another x-ray (fig. 4) of the left femur showed advanced osteomyelitis, with necrosis of the head

The general nutritional status was maintained by augmenting the regular formula with multivitamins, iron and calcium caseinate. The infant fed well and required no parenteral therapy. Weight gain was slow but steady.

After two weeks the child voluntarily moved the left leg, although he resented active movement. At no time was the leg placed in any orthopedic appliance.

On the thirty-seventh hospital day the child was discharged to the parents, who wished to return to their home following the impending honorable release of the father from active service with the U. S. Navy. The parents were advised to secure orthopedic care for the child soon after reaching their destination.

SUMMARY

1. Acute osteomyelitis occurred in a 19 day old infant. This seems to have been of hematogenous origin, and the etiologic agent was a nonhemolytic Staphylococcus aureus cultured from the pus following drainage of a communicating soft tissue abscess.

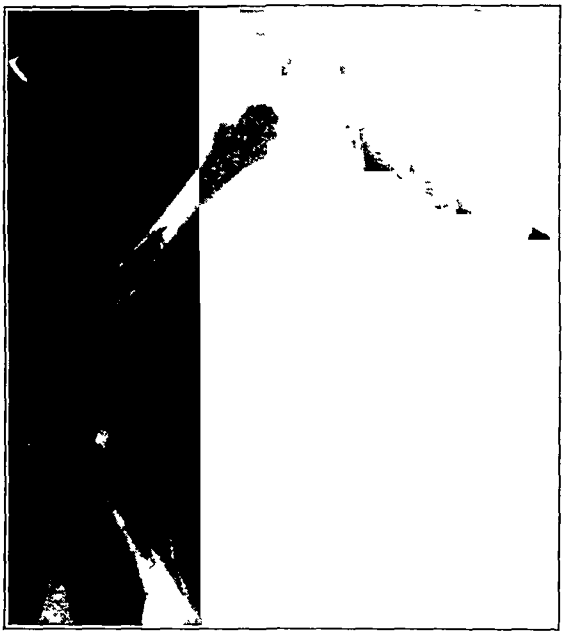

Fig 3—Appearance on the ninth day of hospitalization and eleven days after onset of local tissue swelling: periosteal reaction at the upper end of the left femur, with osteomyelitic process involving the upper third of the bone.

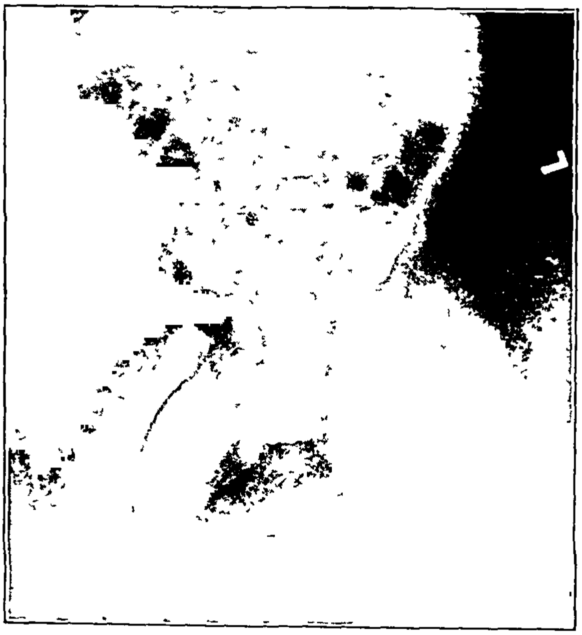

Fig 4.—Advanced osteomyelitic process of the upper third of the left femur on the twenty second hospital day, with loss of the anatomic contour of the head of the bone. Soft tissue calcification is present.

2. Penicillin was demonstrated to be life saving. The infant received a total of 640,000 units of calcium penicillin, given intramuscularly over a ten day period. The coincident reduction in temperature and reversion of the white blood cell count to normal paralleled the improvement in the patient's condition and occurred during the course of penicillin therapy.

3. X-rays showed bone changes in the evolution of the osteomyelitic process.

4. Further care of the patient was interrupted because of the parents' desire to travel home following the father's honorable discharge from the U. S. Navy.

DUODENAL BEZOAR RESULTING FROM PICA AND OBSTRUCTION OF MESENTERY ARTERY

GORDON McHARDY, M.D.
and
DONOVAN C. BROWNE, M.D.
New Orleans

Chronic duodenal dilatation and stasis created by an anomalously positioned superior mesenteric artery compressing the third portion of the duodenum where it traverses the spine is not unusual. This obstructive phenomena is commonly intermittent, varies greatly in degree of severity and most often is concomitant with the habitus asthenicus contributing in the production of the Weir-Mitchell individual, so common and chronic a problem to the gastroenterologist.

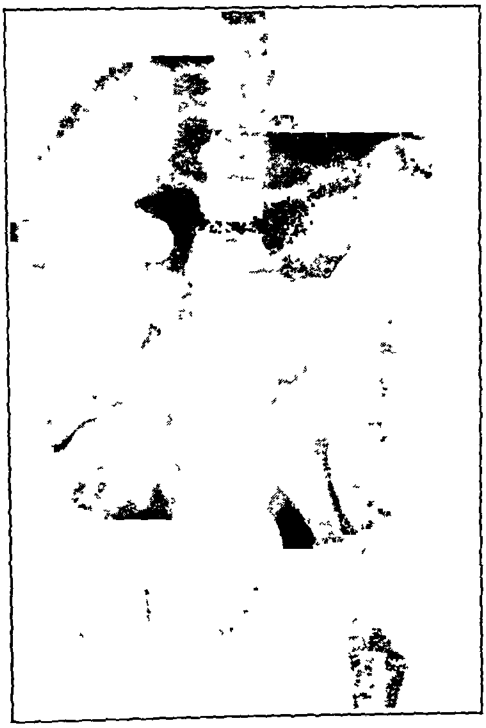

Fig. 1.—Extracolonic foreign bodies revealed with barium enema in vicinity of the right transverse process of the fourth lumbar vertebra.

Predisposition to foreign body retention or bezoar formation would seem likely in such individuals. A multitude of objects found in the duodenum and listed by Kellogg include pins, needles, buttons, coins, wood fragments, bones, nails, knives, spoons, buckles, false teeth, hair, pencils, esophageal instruments, prune and olive pits and string. Their retention therein was in no instance related to the type of duodenal obstruction under consideration. Reported bezoars of the duodenum have all been secondary, resulting from extension of a gastric bezoar. As such they are extremely rare; a primary duodenal bezoar enters into the realm of medical curiosities.

It is therefore justifiable to report a duodenal foreign body which in itemization qualifies as a bezoar. This duodenal accumulation had its causation in a pathologic individual in that organically the patient was proved to have an anomalous mesenteric artery position; mentally she ingested articles conducive to the creation of a bezoar.

REPORT OF CASE

J. P., *a girl aged 6 years, of French extraction,* had experienced *an uneventful childhood until six months* prior to our *seeing her on March 26, 1943.* The referring physician had *observed her for six months,* during which period she had retained a radiopaque foreign body, presumably a coin, in the same position in the enteric tract and had lost 7 pounds (3.2 Kg.). The weight loss in an already malnourished child with quantitative dyspepsia was coupled with episodes of nausea and emesis as the entire symptomatology.

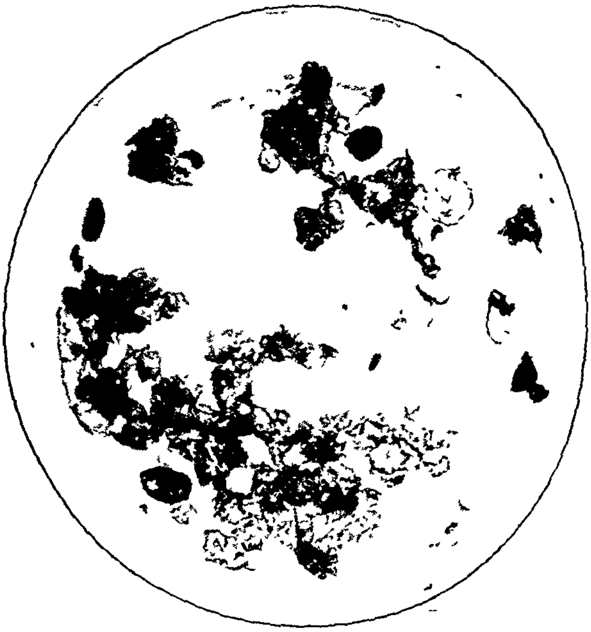

Fig. 2.—Portion of disintegrated bezoar removed from the duodenum at the first operation.

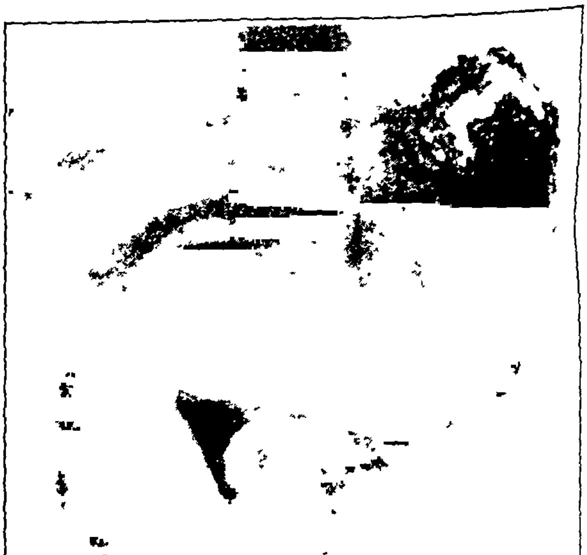

Fig. 3.—Barium delineation of the stomach and duodenum showing the duodenal enlargement and retention.

Physical findings other than evidence of malnutrition and niacin deficiency were those of asthenic habitus and leathery tan skin pigmentation like that of a Mediterranean, despite normal parental skin characteristics.

From the Department of Medicine, Tulane University Medical School, and the Gastrointestinal Department, *Touro Infirmary.*

Positive laboratory findings included a hypochromic microcytic anemia, lambliasis and amebiasis.

X-ray examination of the abdomen on March 26 revealed two radiopaque foreign bodies, one discoid and the other a ring, overlying the right transverse process of the fourth lumbar vertebra. On May 31 an additional foreign body, presumably a button, was present. In the interval the two varieties of intestinal parasites were eradicated. However, the patient's emesis became progressively severe, with apparent partial persistent high intestinal obstruction.

Surgical intervention was elected. On June 9 the bezoar was extracted by Dr. J. D. Rives from a tremendously distended duodenum; it was impossible to mobilize the bezoar back into the stomach. The duodenum was elongated, atonic and of a 3 inch diameter; it was sharply angulated at the site of definitely demonstrable mesenteric compression. There was no intraluminary obstruction. The patient's status at the time contraindicated further surgery.

An inventory of the bezoar revealed kapok, thread, a copper cent, a small gold plated ring, persimmon seeds and hull, prune pits, buttons, hair, watermelon seeds, vegetable débris, wood fragments, bone spicules, string, fragments of cloth and paper.

Temporary improvement and weight ensued on a low residue dietary regimen. However, a year subsequent recurrent symptoms indicated x-ray evaluation, which showed her status unimproved. On this occasion a gastrointestinal visualization demonstrated the obstructed duodenum as illustrated in figure 3.

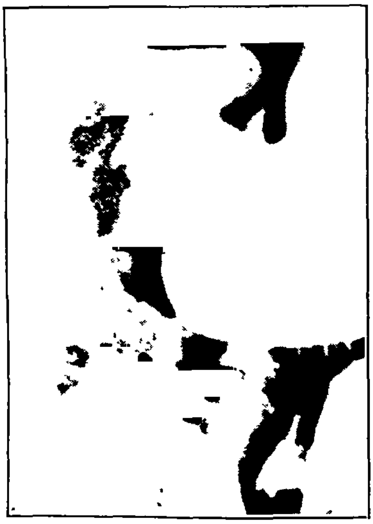

Fig. 4.—Delineation of the satisfactorily functioning duodenojejunostomy with return of essentially normal duodenal tonus.

On July 30 a duodenojejunostomy was done by Dr. Rives. Most recent evaluation on April 9, 1945 showed curative results with a well functioning duodenojejunostomy permitting normal gastrointestinal transfer of even the continued outlandish ingestions of the patient, who during operative convalescence was detected eating kapok from her pillow.

1534 Aline Street, New Orleans 15.

Place of Science in the Scheme of Culture.—This testing of the place of science in the scheme of culture has been general, but the issue has consequences so determining as to deserve and indeed require illustration in a special case. It is a situation which deserves careful analysis. Science having become decisive in many aspects of the practical life, in engineering, in pharmacology, in agriculture, citizens demand opportunity for becoming familiar with contributions now so vital to human comfort, not to say happiness. The orientation of nations differs and differs signally. One conspicuous difference is the American attitude toward science. The universities exhibit this attitude in a striking fashion reflecting, as they do, the national dependence on science.—Cohn, Alfred E.: Minerva's Progress, New York, Harcourt, Brace & Co., 1946.

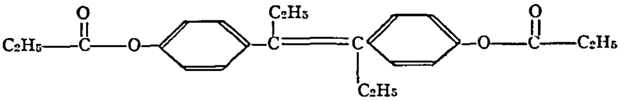
Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

Austin Smith, M.D., *Secretary.*

DIETHYLSTILBESTROL DIPROPIONATE.—The *di*-propionyl ester of α,α′-diethyl-4,4′-stilbenediol.—$C_{24}H_{28}O$— M. W. 380.46.—Diethylstilbestrol diproprionate may be prepared by esterification of diethylstilbestrol with propionic acid chloride and purified by recrystallization from alcohol. It may be represented by the following structural formula:



Actions and Uses.—Diethylstilbestrol diproprionate is used for the same conditions for which estrogenic substances are employed, although it is claimed that reactions such as nausea and vomiting appear to be less frequent with a diproprionate salt than with free diethylstilbestrol when the drugs are administered intramuscularly in oil. Diethylstilbestrol dipropionate is relatively slowly absorbed from the oil depot and causes a lower blood stream concentration, although one of more prolonged duration.

Dosage.—Diethylstilbestrol Dipropionate in Oil is administered intramuscularly. The following average dosage by injection should be modified to meet individual requirements:

Menopause }
Senile vaginitis } from 0.5 to 2 mg. two or three times a week.
Suppression of lactation—5 mg. once or twice daily for a total of from two to four days.

After a therapeutic effect has been obtained, the dosage should be reduced until the minimum effective dose for maintenance has been established.

Tests and Standards.—

Diethylstilbestrol dipropionate occurs as an odorless, tasteless, white, crystalline powder which melts at 105-107 C. It is readily soluble in acetone, benzene, ether, chloroform, hot ethyl alcohol and hot methyl alcohol; soluble in vegetable oils; very slightly soluble in water and dilute mineral acids; and insoluble in alkaline aqueous solutions.

Dissolve 10 mg. of diethylstilbestrol dipropionate in 2 cc. of concentrated sulfuric acid: an orange color is produced which disappears on dilution with water. Add 1 cc. of 50 per cent solution of antimony pentachloride in dry alcohol-free chloroform to 5 cc. of a dilute solution of diethylstilbestrol dipropionate in the same solvent: a red colored solution is produced. The residue obtained in the assay for diethylstilbestrol dipropionate melts at 168-171 C. and responds to tests for diethylstilbestrol.

Dry an accurately weighed specimen of diethylstilbestrol dipropionate to constant weight in a partial vacuum at 80 C.: the loss in weight does not exceed 0.5 per cent. Ignite an accurately weighed specimen of diethylstilbestrol dipropionate after the addition of concentrated sulfuric acid: the residue does not exceed 0.05 per cent. A suspension of 0.1 Gm. of diethylstilbestrol dipropionate in 10 cc. of diluted alcohol is neutral to litmus paper.

Dissolve approximately 0.3 Gm. of diethylstilbestrol dipropionate, accurately weighed, in 10 cc. of a 15 per cent solution of potassium hydroxide in methyl alcohol and heat under reflux for thirty minutes. Cool, dilute with 100 cc. of water, transfer to a separator and acidify with dilute hydrochloric acid. Extract the mixture with four separate portions of ether, combining the ether extracts; wash the ether solution with three separate portions of 5 per cent sodium bicarbonate solution and once with water; decant the ether solution through a small cotton plug into a tared beaker; rinse the separator and cotton plug with fresh ether and evaporate the ether extract in a stream of warm air. Dry the residue to constant weight at 75-80 C.: the weight of the diethylstilbestrol obtained, multiplied by the factor 1.418, is equivalent to not less than 98 per cent nor more than 100.5 per cent of the weight of the specimen.

The following dosage form has been accepted:

Winthrop Chemical Company, Inc., New York

Solution Diethylstilbestrol Dipropionate (in Olive Oil): 0.5 mg. per cc., 1 mg. per cc. and 5 mg. per cc.: 1 cc. ampuls.

HEXAVITAMIN (See The Journal, Aug. 11, 1945, p. 1099).

The following dosage form has been accepted:

Walker Vitamin Products, Inc., Mount Vernon, N. Y.

Capsules Hexavitamin: Each capsule contains 2,500 U. S. P. units of vitamin A, 200 U. S. P. units of vitamin D, 1 mg. of thiamine, 1.5 mg. of riboflavin, 30 mg. of ascorbic acid and 10 mg. of niacinamide.

SATURDAY, MARCH 30, 1946

RETIREMENT OF DR. OLIN WEST, SECRETARY-GENERAL MANAGER

According to the official announcement from the Board of Trustees which appears elsewhere in this issue, Dr. Olin West, Secretary-General Manager of the American Medical Association for more than twenty-three years, retires from his official duties on April 1. The intense devotion of almost a quarter of a century of unremitting diligence in behalf of the progress of the American Medical Association and of its policies for the maintenance of medicine as a profession has taken a considerable toll of his energy.

Dr. Olin West came to the American Medical Association with a record of experience in medicine and public health that especially fitted him for the positions that he assumed. His preliminary education was received at Howard College in Alabama, in which state he was born at Gadsden on July 12, 1874. He graduated from Vanderbilt University School of Medicine, Nashville, Tenn., in 1898. In 1910, after twelve years of practice in Nashville and fifteen years as a member of the faculty of Vanderbilt University, first as instructor and later as assistant professor and associate professor in chemistry, Dr. West became director for the Rockefeller Sanitary Commission and International Health Board in Tennessee. Here he was especially effective in the great campaign against hookworm infection. In 1918 he became secretary and executive officer of the Tennessee State Board of Health and after four years gave up that position to become field secretary of the American Medical Association in association with Dr. Alexander Craig, who was at that time Secretary. Following the death of Dr. Craig, Dr. West was appointed Secretary by the Board of Trustees. Then when Dr. George H. Simmons resigned as Editor and General Manager of the Association in 1924, Dr. West continued in the position of Secretary and succeeded to the duties of General Manager.

In early activities for the organized medical profession Dr. West was president of the Middle Tennessee Medical Association and later secretary of the Tennessee State Medical Association and editor of its journal. His love for the art and tradition of medical science, his great personal compassion, his geniality and his friendliness have endeared him personally to many thousands of American physicans who have met him in office and who have had advantage of his personal counsel and judgment.

The Journal wishes to Dr. West on his retirement many years of healthful life and many hours in which he can devote himself to his family and his friends, realizing at the same time that his interest in medicine and particularly in the advancement of the American Medical Association will never lag. Certainly the committees and the councils of the Association will continue to utilize as far as possible the experience and the judgment which have meant so much toward achieving the high place that the American Medical Association occupies today among medical organizations throughout the world.

BRITAIN'S NATIONAL HEALTH ACT

Regardless of the preliminary publicity and the prolonged incubation period, the announcement of the proposals for the nationalization of medical services in Great Britain was startling. Apparently the British government proposes to take over—in every sense of those words—the hospitals and the medical practices of British physicians. Thus a nation which fought to a successful issue against totalitarianism now proposes to enslave its own medical profession and to make of every one of its physicians a clock-watching civil servant. Men who formerly devoted their lives wholeheartedly to the care of the sick and to the relief of pain and suffering will now be spending their hours trying to satisfy the whims of the bureaucrats and to disencumber themselves from the red tape that bureaucrats inevitably weave. What the government leaders urge as a step forward in the prevention and control of disease will be considered by representatives of medical science everywhere as one of the most backward steps ever conceived for a civilized nation.

In an address on "The Science and Art of Medicine" delivered by Sir Lionel Whitby as his inaugural lecture as regius professor of physic in Cambridge University, the distinguished British physician said:

> The simple facts are that medicine is both a science and an art. It is true that medicine will never be an exact science, because the normal variations in individuals have such a wide range that automatic and mechanical treatment is prohibited,

> whilst every patient requires a different method of approach according to his psychology. This, the frequently ridiculed bedside manner, which secures the confidence of the patient, is of fundamental importance in practice; it is an art which is inborn and not acquired. Nevertheless, even the most confirmed artist cannot now neglect to keep up to date with the facts and findings of science upon which his diagnosis and treatment must be based. Nor will the artistic claim be very sympathetically received by a court of law, should the claimant have neglected the scientific aspect. But one of the attractions of the profession is the personal and individual character of its practice: the latitude with which a qualified doctor may exercise his own judgment, express his own opinions and practice his own art. *This, indeed, is one of the strongest objections to nationalization and standardization. If the profession of medicine be robbed of its scope for individuality, the soul will go out of it* [italics ours].

Thus from a British leader comes new emphasis on the points that great American physicians have emphasized in their opposition to socialized or political medicine.

During the great war just ended scientific medicine advanced tremendously. The development of the antibiotic drugs, of blood derivatives, of new surgical technics, of controls over insect borne diseases are among the steps that will increase life expectancy and even perhaps reduce the incidence of such diseases as pneumonia and the venereal diseases, as typhoid and diphtheria have been decreased. In the face of constant advancement and ever diminishing morbidity and mortality the politicians would promote a revolution in methods of medical education, medical research and medical care, unthinking that the steps they propose may halt if not destroy the scientific medical forces that have yielded these results.

Especially sad is the British proposal that the government take over the private hospitals which have been the pride of the democracies for more than a century. Our Catholic, Protestant and Jewish hospitals have grown out of that fundamental tenet of all great religions that the care of the sick is one of the highest spiritual motives to which man can attain. Britain's act proposes that these hospitals become creatures of an automatic routine ridden government bureaucracy. Thus sick human beings would become cards in a government index representing robots, which, when incapacitated, would receive the ministrations of employed doctors reduced to the status of subservient mechanics.

Perhaps the long controversial debate to which this arbitrary and revolutionary legislation is certain to be subjected in the British parliament will develop some means for retaining in Great Britain the spirit and the tradition that have earned for British medicine up to now the respect of scientists throughout the world.

STREPTOMYCIN THERAPY OF WHOOPING COUGH

Encouraging data as to the therapeutic effects of streptomycin in the treatment of experimental murine pertussis are reported by Bradford and Day[1] of the Department of Pediatrics, University of Rochester. Three week old Swiss mice were inoculated intranasally with 0.05 cc. of a suspension of freshly isolated Hemophilus pertussis. The inoculations were usually made in subgroups of 5 mice, the doses given to the different subgroups being approximately 125, 31.2, 7.8, 1.9 and 0.47 million micro-organisms, or a 1:4 serial dilution of the initial suspension. After inoculation the mice were kept under uniform environmental conditions for a ten day period, with deaths recorded daily. At the end of the ten day period necropsies were performed on the surviving mice and cultures made from their lungs.

In a typical experiment 40 mice were inoculated with 1:4 serial dilutions in five duplicate subgroups. Four hours later, five subgroups were injected subcutaneously with 130 units of streptomycin. This dose was repeated every six hours for the next five days. Five control or untreated subgroups were injected with an equal volume (0.2 cc.) of saline solution. In the five treated subgroups there was but one fatality. This was in the subgroup given the largest infectious dose (125 million H. pertussis). Of the 19 surviving mice in the treated subgroups, 14 had sterile lungs at the end of ten days. Among the untreated control subgroups 9 mice died. But 2 of the 11 survivors in the untreated groups gave negative pulmonary cultures. The calculated 50 per cent minimum lethal dose for the treated groups was more than 125 million micro-organisms. For the untreated groups the calculated 50 per cent minimum lethal dose was 12.7 million. This suggests that there was a tenfold increase in natural pertussis resistance as the result of streptomycin therapy.

In a second experiment with a slightly more virulent strain of H. pertussis there was a 100 per cent survival with sterile lungs following 250 unit doses of streptomycin given intra-abdominally four times daily for five days. In the untreated control subgroups (20 mice) there were but 5 survivors. Only 1 of these had sterile lungs. In a parallel therapeutic test with penicillin there were 7 survivors with 2 sterile lungs. Penicillin is thus without therapeutic promise.

The therapeutic value of streptomycin as indicated by these and other data is sufficient to justify its trial in human medicine. Clinical trials are now in progress in the Department of Pediatrics, Rochester University.

---

Current Comment

THE PERIODICITY OF INFLUENZA

Many attempts have been made to find a cyclic pattern for influenza and to determine its periodicity. In a recent communication[1] from the Commission on Acute Respiratory Diseases the previous theories have been reviewed and the problem reconsidered in the light of experiences between 1920 and 1944. The report points out that there have been sixteen widespread epidemics of influenza in the United States since 1920. The analysis of the patterns of these epidemics led to advancing the theory that they could be accounted for on the basis of two specific recurring infections. According to the interpretation it appears that influenza A has a cycle of two to three years and influenza B a cycle of four to six years. Evidence that other influenza viruses have caused epidemics of a widespread nature during the past twenty-five years was not obtained. The hypothesis is also advanced that the occurrence of influenza epidemics is determined principally by the balance relationship between immune and susceptible persons in the community. The commission has, moreover, hazarded a forecast of the probability of occurrence of further epidemics of influenza within certain time limits. The study has been hampered by the inability to determine which influenza viruses were responsible for the earlier epidemics; only recently could this be determined. The prophecy made may or may not prove accurate. Whenever a forecast of this type can be made successfully the possibilities of controlling epidemics of influenza will be greatly improved.

PLANNING BY THE COMMONWEALTH FUND

In the Annual Report of the Commonwealth Fund, 1945,[1] Mr. Barry C. Smith takes the President's health message as a challenge to American medicine to prove that it can do the job better than can the government. "When wholesale extension of medical and hospital services is proposed," says the report, "it is time to ask more critically than ever before whether those services are as nearly right for the functions they are intended to fulfil as hard, clear thinking can make them." Mr. Smith feels that the most conspicuous defect in the medical picture is the paucity of well trained people. The previous experience of the Commonwealth Fund leads to the conviction that rural medicine will continue to lag until rural physicians are far better trained than they are today and that public health service lags for a lack of health officers competent to do more than a routine job. Mr. Smith says also that the number of well or indifferently trained psychiatrists is too few to cope with the present distribution of mental disease and marginal disability. Moreover, the report asserts it is not alone the quantity but the quality of professional training that needs attention. Because of the many questions that have not been solved as to patterns of action, the Commonwealth Fund is determined to keep its relatively small resources and its policy fluid until the place of philanthropic funds in these shifting patterns becomes clear. For that reason the objectives to be supported by this foundation during the next period will include:

1. Sound training for professional and technical workers in strategic phases of health maintenance.
2. The broadening and integration of the basic concepts of medical care so that it may become truly comprehensive.
3. The practical encouragement of human curiosity as the fountainhead from which medical knowledge renews itself.

Among the special projects in which this fund will be engaged is an attempt to increase the educational qualifications of certain hospitals by supplying them with educational supervisors who will furnish guidance in the education of house officers. In several institutions attempts are being made to integrate psychiatry and internal medicine. Most important, however, is a large scale experiment which is being developed near Rochester, N. Y., with a view to showing how the existing resources of rural medicine can profitably be supplemented by those of a regional center. The plan involves a linking of the rural hospitals in seven counties near Rochester with the institutions in Rochester with a view to providing a high type of medical care throughout the area.

LOS ANGELES COUNTY MEDICAL ASSOCIATION CELEBRATES SEVENTY-FIFTH ANNIVERSARY

On the last evening of January in 1871 a group of seven Los Angeles physicians organized the Los Angeles County Medical Association. At that time the official population of Los Angeles was 6,598 and that of Los Angeles County, which included what is now Orange County, was about 16,000. During the interval since its organization Los Angeles has become one of the world's largest cities and the county one of the most heavily populated in the country. The Los Angeles County Medical Association has grown correspondingly. Its Bulletin for January 31 celebrates with a seventy-fifth anniversary number, reviewing the history of the association. This issue of the Bulletin contains information of historical value. Both the Los Angeles County Medical Association and its Bulletin can be congratulated on their contributions to the health of the community and to the advancement of the medical profession during a period of phenomenal growth.

RADIO TRANSCRIPTS ON MEDICAL CARE PROBLEMS

Elsewhere in this issue (page 881) appears an announcement of a series of six radio transcriptions on subjects of economic medicine. These have been prepared by the Council on Medical Service and Public Relations in cooperation with the Bureau on Health Education of the A. M. A. They represent an additional service furnished by the Council and the Bureau which is now available to local medical societies.

NATIONAL HEALTH PROGRAM OF THE AMERICAN MEDICAL ASSOCIATION

Adopted by the Board of Trustees and the Council on Medical Service, Feb. 14, 1946

1. The American Medical Association urges a MINIMUM STANDARD OF NUTRITION, HOUSING, CLOTHING AND RECREATION as fundamental to good health and as an objective to be achieved in any suitable health program. The responsibility for attainment of this standard should be placed as far as possible on the individual, but the application of community effort, compatible with the maintenance of free enterprise, should be encouraged with governmental aid where needed.

2. The provision of PREVENTIVE MEDICAL SERVICES through professionally competent health departments with sufficient staff and equipment to meet community needs is recognized as essential in a health program. The principle of federal aid through provision of funds or personnel is recognized with the understanding that local areas shall control their own agencies as has been established in the field of education. Health departments should not assume the care of the sick as a function, since administration of medical care under such auspices tends to a deterioration in the quality of the service rendered. Medical care to those unable to provide for themselves is best administered by local and private agencies with the aid of public funds when needed. This program for national health should include the administration of MEDICAL CARE, INCLUDING HOSPITALIZATION TO ALL THOSE NEEDING IT BUT UNABLE TO PAY, such medical care to be provided preferably by a physician of the patient's choice with funds provided by local agencies with the assistance of federal funds when necessary.

3. The procedures established by modern medicine for advice to the prospective mother and for ADEQUATE CARE IN CHILDBIRTH should be made available to all at a price that they can afford to pay. When local funds are lacking for the care of those unable to pay, federal aid should be supplied with the funds administered through local or state agencies.

4. The child should have throughout infancy PROPER ATTENTION, INCLUDING SCIENTIFIC NUTRITION, IMMUNIZATION AGAINST PREVENTABLE DISEASE AND OTHER SERVICES INCLUDED IN INFANT WELFARE. Such services are best supplied by personal contact between the mother and the individual physician but may be provided through child care and infant welfare stations administered under local auspices with support by tax funds whenever the need can be shown.

5. The provision of HEALTH AND DIAGNOSTIC CENTERS AND HOSPITALS necessary to community needs is an essential of good medical care. Such facilities are preferably supplied by local agencies, including the community, church and trade agencies which have been responsible for the fine development of facilities for medical care in most American communities up to this time. Where such facilities are unavailable and cannot be supplied through local or state agencies, the federal government may aid, preferably under a plan which requires that the need be shown and that the community prove its ability to maintain such institutions once they are established (Hill-Burton bill).

6. A program for medical care within the American system of individual initiative and freedom of enterprise includes the establishment of VOLUNTARY NONPROFIT PREPAYMENT PLANS FOR THE COSTS OF HOSPITALIZATION (such as the Blue Cross plans) and VOLUNTARY NONPROFIT PREPAYMENT PLANS FOR MEDICAL CARE (such as those developed by many state and county medical societies). The principles of such insurance contracts should be acceptable to the Council on Medical Service of the American Medical Association and to the authoritative bodies of state medical associations. The evolution of voluntary prepayment insurance against the costs of sickness admits also the utilization of private sickness insurance plans which comply with state regulatory statutes and meet the standards of the Council on Medical Service of the American Medical Association.

7. A program for national health should include the administration of MEDICAL CARE, INCLUDING HOSPITALIZATION, TO ALL VETERANS, such medical care to be provided preferably by a physician of the veteran's choice, with payment by the Veterans Administration through a plan mutually agreed on between the state medical association and the Veterans Administration.

8. RESEARCH FOR THE ADVANCEMENT OF MEDICAL SCIENCE is fundamental in any national health program. The inclusion of medical research in a National Science Foundation, such as proposed in pending federal legislation, is endorsed.

9. The services rendered by VOLUNTEER PHILANTHROPIC HEALTH AGENCIES such as the American Cancer Society, the National Tuberculosis Association, the National Foundation for Infantile Paralysis, Inc., and by philanthropic agencies such as the Commonwealth Fund and the Rockefeller Foundation and similar bodies have been of vast benefit to the American people and are a natural outgrowth of the system of free enterprise and democracy that prevail in the United States. Their participation in a national health program should be encouraged, and the growth of such agencies when properly administered should be commended.

10. Fundamental to the promotion of the public health and alleviation of illness are WIDESPREAD EDUCATION IN THE FIELD OF HEALTH and the widest possible dissemination of information regarding the prevention of disease and its treatment by authoritative agencies. Health education should be considered a necessary function of all departments of public health, medical associations and school authorities.

MEDICINE AND THE WAR

ARMY

ENLISTED MEN ASSIGNED TO THE ARMY SPECIALIZED TRAINING PROGRAM

Following is a government release known as ASF Cir. 56 discussing the disposition of enlisted men assigned to the Army Specialized Training Program for medical training:

2. *Disposition of enlisted men assigned to ASTP for medical training.* *a.* Enlisted men assigned to ASTP for medical training who are scheduled to graduate from medical school before 1 July 1946 will not be separated from the Army regardless of age, length of service, critical score, or by virtue of having three or more children under 18 years of age. They will not be permitted to enlist in the Regular Army. They may be separated under existing regulations pertaining to discharge of enlisted men because of undue hardship or because of importance to national health, safety or interest. They will not be separated for any other reasons except as individually authorized by the War Department.

b. Enlisted men assigned to ASTP for medical training who are not scheduled to graduate from medical school prior to 1 July 1946 will be disposed of as follows:

(1) Those enlisted men who meet current War Department criteria for separation may be discharged.

(2) Those enlisted men who are eligible for discharge under 30 April or 30 June criteria and who do not plan to continue their medical studies may be reassigned within the service command until the date of their discharge if their services are needed. If their services are not needed, they will be discharged.

(3) Those enlisted men who do not meet War Department criteria for separation, who do not plan to continue their medical studies, or are not acceptable at an accredited medical school will be transferred to Brooke Army Medical Center, Fort Sam Houston, Texas.

(4) Those enlisted men who are not eligible for separation who signify their intention to continue their medical studies and are acceptable at an accredited medical school will be released from active federal service and transferred to the Enlisted Reserve Corps. Authority for such release will be section I, AR 615-363, and this circular. These men will furnish a certificate from the dean or other similar official of a medical school approved by the Council on Medical Education and Hospitals of the American Medical Association.

HOLD OPHTHALMOLOGIC CONFERENCE AT VALLEY FORGE

A trisession conference of civilian doctors and Army Medical Corps officers specializing in ophthalmology and related plastic surgery was held recently at Valley Forge General Hospital, Phoenixville, Pa. A total of 70 ophthalmologic cases were examined and discussed during the conference, which was opened with a discussion on "Military Plastic Surgery" by Lieut. Col. Bradford Cannon, chief of the Valley Forge General Hospital plastic surgery section. Lieut. Col. Phillips Thygeson, chief of the eye, ear, nose and throat section, presided.

MEDICAL CARE FOR DEPENDENTS

Plans to provide complete and free medical care for dependents of U. S. Army personnel who will arrive in Germany from the United States are now being formed. A particular effort will be made by the Preventive Medicine Division of the Surgeon General's Office to furnish parents with all known facts on contagious diseases prevalent in Germany, especially those to which children are most susceptible, and methods of preventing these diseases. A child health program will be handled by army physicians experienced in the field.

APPOINTED DIRECTOR OF SURGICAL CONSULTANTS DIVISION

Col. Frank L. Cole, formerly commanding officer of Wakeman Hospital Center, Camp Atterbury, Indiana, was recently assigned to relieve Col. Michael E. DeBakey as director of the Surgical Consultants Division, Office of the Surgeon General. Dr. Cole graduated from the University of Illinois College of Medicine, Chicago, in 1914 and was commissioned in the Army Medical Corps in 1917.

ASSIGNED TO ARMY INSTITUTE OF PATHOLOGY

Col. Raymond O. Dart, deputy chief surgeon for the American Forces in the Western Pacific, was recently appointed assistant director of administration, Army Institute of Pathology. Dr. Dart graduated from Rush Medical College, Chicago, in 1916 and entered the service in 1917.

ANNUAL MEETING OF ARMY EPIDEMIOLOGICAL BOARD

The annual meeting of the Army Epidemiological Board will be held April 15-16 in the board room of the National Academy, National Research Building, 2101 Constitution Avenue, Washington, D. C.

ARMY AWARDS AND COMMENDATIONS

Colonel Bruce P. Webster

Col. Bruce P. Webster, New York, was recently presented the Legion of Merit "for exceptionally meritorious conduct in the performance of outstanding services in the Southwest Pacific Area from Sept. 16, 1944 to Oct. 15, 1945. As surgeon, Replacement Command, United States Army Forces in the Far East, Colonel Webster developed the Medical Service within the Replacement Command into an outstanding agency and in addition planned and executed the expeditious processing and assignment of incoming medical department personnel. Subsequently, as director of the control division, Chief Surgeon's Office, General Headquarters, United States Army Forces, Pacific, he was highly successful in initiating and supervising effective measures for the control of venereal disease, care of liberated prisoners of war and medical training of amphibious troops. As senior representative, Office of the Chief Surgeon, Advance Echelon, General Headquarters, he displayed unusual resourcefulness in establishing an echelon of the policies for the expeditious recovery, hospitalization, evacuation and processing of liberated prisoner of war patients. Through his ceaseless effort, extensive professional skill and devotion to duty, Colonel Webster made a distinct contribution to the success of medical service in the Southwest Pacific Area." Dr. Webster graduated from McGill University Faculty of Medicine, Montreal, in 1925 and entered the service July 1, 1942.

Lieutenant Colonel Ronald H. Kettle

The Bronze Star was recently awarded to Lieut. Col. Ronald H. Kettle of the Norwich State Hospital, Norwich, Conn., "for meritorious service in connection with military operations against the enemy from Dec. 5, 1944 to Sept. 2, 1945." Dr. Kettle graduated from Queen's University Faculty of Medicine, Kingston, Ont., in 1928 and entered the service Oct. 17, 1942.

Major Franklin D. Rodabaugh

Major Franklin D. Rodabaugh, Toledo, was recently awarded the Legion of Merit for "exceptionally meritorious conduct in the performance of outstanding services from May 11, 1944 to Jan. 22, 1945." Dr. Rodabaugh graduated from Ohio State University College of Medicine, Columbus, in 1941 and entered the service Aug. 1, 1942.

Captain Robert E. Vorisek

The Bronze Star was recently awarded to Capt. Robert E. Vorisek, New York, for "meritorious achievement in connection with military operations against the enemy on Mindanao, Philippine Islands, from April 17 to Aug. 1, 1945." Dr. Vorisek graduated from Long Island College of Medicine, Brooklyn, in 1941 and entered the service Dec. 30, 1942.

NAVY

EXAMINATIONS FOR APPOINTMENTS AS ASSISTANT SURGEONS

The Bureau of Medicine and Surgery, Navy Department, will convene boards of medical examiners and supervisory naval examining boards May 6-10 at twenty-nine continental United States naval hospitals for the purpose of conducting physical and professional examinations of eligible candidates for appointment to the grades of assistant surgeon and acting assistant surgeon in the U. S. Navy.

The primary purpose behind the setting up of these examinations for appointment to the grade of assistant surgeon has been to establish a channel of appointment for medical officers of the U. S. Naval Reserve who have not served on active duty in commissioned rank for a period of six months. The medical officers of the Naval Reserve within this category are those who have been deferred from active duty under the provisions of the 9-9-9 program and whose total service in commissioned status has been purely inactive in that their training under the conditions of this program have been performed in civilian medical institutions. This is not intended, however, to exclude from participation in these examinations doctors having no affiliation with the Navy, and it is desired to emphasize that applications are invited from all physicians who meet the requirements for appointment to the Medical Corps of the U. S. Navy.

The examinations to be conducted for appointment to the grade of acting assistant surgeon for naval internship will be a departure from the current system of intern appointments in that during the latter years of the war it has been the practice of the Navy Department to appoint qualified medical school graduates to the rank of lieutenant (jg), (MC), U.S.N.R. for naval intern training from a review of credentials submitted by candidates to the Bureau of Medicine and Surgery. In line with the schedule of demobilization and a transition to peacetime operations it has been deemed necessary that the bureau resume the prewar procedure of professionally examining senior medical students for appointment to the grade of acting assistant surgeon in the rank of lieutenant (jg), (MC), U.S.N., for naval internship on completion of their medical education and thus insure the availability of an adequate number of properly qualified appointees at appropriate periods.

The general qualifications for appointment in the Medical Corps of the U. S. Navy are as follows:

> A candidate is required to be a citizen of the United States, of more than 21 but less than 32 years of age at the time of appointment and a graduate of or a student in a medical school listed as approved by the Council on Medical Education and Hospitals of the American Medical Association. The age, physical and citizenship requirements for appointment as acting assistant surgeon and assistant surgeon in the Medical Corps of the U. S. Navy are the same.
>
> Candidates for appointment as assistant surgeon are required to be graduates of medical schools listed as approved by the Council on Medical Education and Hospitals of the American Medical Association who have completed their intern training in a civilian or naval hospital or who will complete such training within four months of the date of the examination and who are physically and in other respects qualified.
>
> A candidate for appointment as acting assistant surgeon for intern training is required to be a third or fourth year medical student enrolled in a medical school listed as approved by the Council on Medical Education and Hospitals of the American Medical Association. Third year medical students may apply only for an examination which will be held subsequent to date of completion of their third year of medical school. If found to be physically, professionally and in other respects qualified, successful candidates will receive their appointments on satisfactory completion of their medical school education. For further information, application forms for appointment and other data address the Bureau of Medicine and Surgery, Navy Department, Washington 25, D. C.

The examination will be given at the naval hospitals in Annapolis, Md.; Astoria, Ore.; Bainbridge, Md.; Bethesda, Md.; Brooklyn; Camp LeJeune, N. C.; Charleston, S. C.; Chelsea, Mass.; Corpus Christi, Texas; Dublin, Ga.; Great Lakes, Ill.; Jacksonville, Fla.; Key West, Fla.; Long Beach, Calif.; Mare Island, Calif.; Memphis, Tenn.; New Orleans; Newport, R. I.; Norman, Okla.; Oakland, Calif.; Parris Island, S. C.; Pensacola, Fla.; Philadelphia; Portsmouth, N. H.; Portsmouth, Va.; Quantico, Va.; Sampson, N. Y.; San Diego, and Seattle.

NAVY AWARDS AND COMMENDATIONS

Rear Admiral Luther Sheldon Jr.

The Legion of Merit was recently presented to Rear Admiral Luther Sheldon Jr., who is now medical officer for the Fifth Naval District, Norfolk, Va., for exceptionally meritorious conduct in the performance of service to the government as assistant to the chief of the Bureau of Medicine and Surgery, Navy Department, from June 26, 1940 to Nov. 25, 1944. "By his broad vision, professional integrity and tireless efforts in discharging the responsibilities of this important duty," said the citation, "Rear Admiral Sheldon rendered immeasurable assistance to the chief of the bureau in rapidly expanding hospital facilities within the Continental United States and at advance bases to meet the requirements of increased activities in the Navy and Marine Corps. His profound understanding and meticulous care in handling the problems of procurement and the training of medical officers, dental officers, nurses and enlisted hospital corpsmen were a distinct asset in the effective functioning of the bureau. His outstanding service in the successful fulfilment of this exacting assignment reflects the highest credit on Rear Admiral Sheldon and the United States Naval Service." Dr. Sheldon graduated from the University of Michigan Medical School, Ann Arbor, in 1909 and entered the service Feb. 1, 1911.

Captain Robert Faust

A Letter of Commendation was recently presented to Capt. Robert Faust, Wichita, Kan., "for meritorious service in the performance of his duties in the medical section, Logistics Division, on the Staff of the Commander in Chief, United States Pacific Fleet and Pacific Ocean Areas, from Jan. 17 to Sept. 1, 1945. Captain Faust displayed outstanding professional ability, sound judgment and initiative in the preparation of plans for the care and treatment of the sick and wounded, implementation of improved technics in evacuation and treatment of casualties, preparation of medical sections of operations plans and plans for and staff supervision over medical installations in connection with the development and roll up of bases. His conduct and devotion to duty were at all times in keeping with the highest traditions of the United States Naval Service." Dr. Faust graduated from the University of Kansas School of Medicine, Kansas City, in 1928 and entered the service June 28, 1928.

Captain Guy Fish

The Bronze Star was recently presented to Capt. Guy Fish, Indian Lake, N. Y. The citation accompanying the award read "For meritorious service in connection with operations against the enemy as medical officer on the staff, Commander Aircraft Central Pacific Force, Commander Forward Area Central Pacific and Commander Marianas from Jan. 20, 1944 to Sept. 22, 1945. During this period he was in a large measure responsible for the establishment, development and administration of medical facilities in the Marshall, Marianas, Western Caroline and Volcano islands. In addition, he assisted in supervising the evacuation of the wounded by aircraft and surface vessels during military operations of great importance. By his zeal, cheerfulness and outstanding professional and administrative ability he contributed materially to the success of the Central Pacific campaign. His complete devotion to duty and conduct throughout were in keeping with the highest traditions of the United States Naval Service." Dr. Fish graduated from Albany (N. Y.) Medical College in 1915 and entered the service Jan. 1, 1921.

ORGANIZATION SECTION

Official Notes

RESIGNATION OF DR. OLIN WEST; APPOINTMENT OF DR. GEORGE F. LULL AS GENERAL MANAGER AND AS SECRETARY PRO TEM.

Following the resignation of Dr. Olin West as Secretary and General Manager of the American Medical Association, the Board of Trustees has appointed Dr. George F. Lull as General Manager of the Association, beginning April 1, 1946 and has elected him Secretary of the Association until the next annual session of the Association, to fill the unexpired term of Dr. West.

BOARD OF TRUSTEES,
AMERICAN MEDICAL ASSOCIATION,
R. L. SENSENICH, Chairman.

Medical Legislation

MEDICAL BILLS IN CONGRESS

National Medical Research Foundation

Congressman Stevenson, Wisconsin, has introduced H. R. 5715, a bill to establish in the executive branch of the government an independent agency to be known as the National Medical Research Foundation to initiate, conduct and support scientific research with respect to the cause and cure of cancer, poliomyelitis, rheumatic fever, Bright's disease, hay fever, asthma, arthritis, leukemia, encephalitis, arteriosclerosis, aplastic anemia and rheumatic heart disease.

Hospital Construction

H. R. 5407 has passed the House, a bill to grant to the Federal Works Administrator certain powers with respect to site acquisition, building construction and purchase of buildings. When this bill was considered in the House, March 18, Congressman Elliott, California, submitted an amendment authorizing an appropriation of $50,000,000 for use by the Federal Works Administrator in making grants to public and private agencies for the construction of hospital facilities. The amendment was rejected on a point of order made by Congressman Wadsworth, New York.

Commission for the Physically Handicapped

Hearings have been scheduled by a subcommittee of the House Committee on Labor on H. R. 5206, a bill to establish a Federal Commission for the Physically Handicapped in the Department of Labor. The hearings will begin on April 30 and will conclude, it is contemplated, on May 4. This bill, among other things, proposes to transfer to the federal commission to be created all functions of the Office of Vocational Rehabilitation now in the Federal Security Agency. The bill would establish in the commission separate divisions for special work with the deaf, the hard of hearing, cardiac patients, the tuberculous, the poliomyelitic, the epileptic, amputees and any other large or distinct groups of physically handicapped.

Miscellaneous

H. J. Res. 324, introduced by Congressman Norrell, Arkansas, proposes to request the President to issue a proclamation designating the 28th day of October of each year as National Arthritis Day. S. 1914, introduced by Senator Langer, North Dakota, proposes to authorize to be appropriated such sums as may be necessary to enable the Federal Security Administrator to make loans to nonprofit organizations to assist them to finance the construction of domiciliary facilities for the aged or the blind. The House Committee on Military Affairs has favorably reported H. R. 5626, proposing to authorize the Veterans Administration to appoint and employ retired officers without affecting their retired status. The authority to employ retired commissioned or retired warrant officers will be effective for a period of five years.

STATE LEGISLATION

California

Bill Enacted.—S. 3-X has become chapter 129 of the Laws of 1946. It authorizes the acquisition of land and buildings for temporary state hospital facilities, such property to be operated by the department of mental hygiene on a temporary basis as temporary state mental institutions.

Idaho

Bill Enacted.—H. 16-X was approved March 9, 1946. It authorizes an appropriation to the department of public health for the purpose of providing tuberculosis hospitalization and relief.

Kentucky

Bills Passed.—H. 171 passed the senate March 20. It proposes the enactment of a law authorizing the establishment, maintenance and operation of medical service plan corporations. "Medical services" means the "general and usual services rendered and care administered by doctors of medicine." "Participating physician" would mean a "doctor of medicine licensed to practice medicine and surgery in this state under the provisions of the medical practice act" who agrees in writing to perform the services specified by the subscription certificates. H. 300 passed the senate March 15. To amend the law relating to pharmacies and drugs, it proposes to make it unlawful to sell at retail any drug which contains any quantity of aminopyrine, barbituric acid, cinchophen, dinitrophenol, pituitary, sulfanilamide, thallium acetate, thyroid, or their derivatives, or a drug or device the label of which bears a statement that it is to be dispensed or sold only by or on the prescription of a physician, dentist or veterinarian, unless such drug is sold on a written prescription signed by a member of the medical, dental or veterinary profession who is licensed by law to administer such drug or device, and its label bears the name and place of business of the seller, the serial number and date of such prescription, and the name of such member of the medical, dental or veterinary profession. S. 152 passed the senate March 13. To amend the law relating to the practice of pharmacy, it proposes that any one who, while in the service of the armed forces, was regularly employed for a period of not less than twelve months in the preparation and dispensing of drugs and medicines and who, in addition thereto, has successfully completed at least two years of study in a recognized college of pharmacy may apply for a pharmacist's license.

Mississippi

Bills Introduced.—H. 699 was previously reported as proposing to authorize the state board of examiners to proceed by injunction to prohibit any person from practicing any profession licensed under the supervision of said board when such person is not duly licensed so to practice. This bill was amended in the house on March 14 by proposing to exempt from its provisions persons practicing chiropractic, osteopathic or veterinary sciences. H. 893, to amend the law relating to ad valorem taxes, proposes to exempt from such tax all plants manufacturing, processing or preparing dentifrices, medicines, drugs or pharmaceuticals. H. 974 proposes an appropriation for the purpose of providing a site for the construction and erection of a general children's hospital for the care and treatment of sick, injured and infirm children and children who are the victims of infantile paralysis or other crippling diseases or infirmities. H. 1016 proposes that any student nurse who takes training provided for nurses in any hospital in the state, supported in whole or in part by state funds having a registered nurse in charge, is authorized to take the examination to become a registered nurse, and if a passing grade is made on such examination such a student nurse is entitled to all rights and benefits now provided for registered nurses. S. 414, relating to the transport of intoxicating liquor into the state, proposes to authorize the issuance of permits for the importation of alcohol for scientific or mechanical purposes by and to such scientific institutions, universities and colleges as are authorized to secure the same free of tax under the laws of the United States and alcohol by and to hospitals and sanatoriums for medical use in such hospitals and sanatoriums, and for the importation and transportation of alcohol to and by any apothecary, druggist, pharmacist or manufacturing agency who shall need the same for such purpose.

Bills Passed.—H. 72 passed the senate March 19. It proposes the creation of a four year medical school as a department of the University of Mississippi which shall be operated as a class A medical school in accordance with the "Council of Medical Education" of the American Medical Association. H. 994 passed the house March 20. It proposes an appropriation to be used and expended by the state board of health and the state department of education in cooperation with the international health division of the Rockefeller Foundation and the general education board, respectively, in carrying out a program of coordinated school, health and nutrition services. S. 181 passed the senate March 13. To amend the law relating to the issuance of marriage licenses, it proposes that both parties applying for a license to marry shall submit to a thorough medical examination by an active licensed physician in Mississippi, by a physician licensed to practice in any or all of the other states of the Union or the District of Columbia, by a commissioned medical officer on active duty in the armed forces of the United States or by a medical officer of the United States Public Health Service, provided said medical examination may be made free of charge by any full time county health officer licensed to practice medicine in Mississippi if the person examined is unable to pay for same. Medical examinations would include a standard serologic test or tests for syphilis.

Missouri

Bills Passed.—S. 343 passed the senate March 12. It proposes the creation of a bipartisan board of six members to be known as the Missouri State Board of Medical Examination and Registration to register and license persons for the practice of medicine and surgery, midwifery and chiropody, and proposes further to transfer the records now in the possession of the department of medical licensure of the state board of health of Missouri to the Missouri State Board of Medical Examination and Registration. S. 433 passed the senate March 19. It proposes to transfer to the state board of chiropody certain powers relating to licensing and registration of practitioners heretofore vested in the state board of health. S. 434 passed the senate March 19. Relating to the licensing of midwives, it proposes to transfer to the division of registration and examination of the state department of education certain powers heretofore vested in the state department of health. S. 456 passed the senate March 19. It proposes the creation of a division of the state department of education to be known as the division of registration and examination and assigns as boards of said division the state board of medical examiners, state board of osteopathic registration and examinations, state board of chiropractic examiners and others.

New Jersey

Bill Passed.—A. 164 passed the assembly March 19. To amend the medical practice act, it proposes an addition to the board of medical examiners of a chiropodist to have equal rights and privileges in all matters affecting chiropody.

Bills Enacted.—A. C. R. 3 was filed with the secretary of state February 11. The adopted resolution proposes the enactment of an unemployment sickness compensation law and submits a proposal to the legislature constituting such a law. A. 69 has become chapter 22 of the Laws of 1946. It authorizes the establishment and maintenance of blood banks to collect, process, store and distribute human blood and the various human blood derivatives, including special therapeutic and diagnostic serums which are deemed of value in the treatment of sick and injured persons and the prevention of certain diseases.

New York
